VMware vSphere 7.0

Table of Contents

Release Notes **75**
VMware vSphere 7.0 Release Notes **75**
VMware vCenter Server Photon OS Security Patches **96**
ESXi Update and Patch Release Notes **110**
VMware ESXi 7.0 Update 3w Release Notes 110
VMware ESXi 7.0 Update 3v Release Notes 140
VMware ESXi 7.0 Update 3s Release Notes 216
VMware ESXi 7.0 Update 3r Release Notes 246
VMware ESXi 7.0 Update 3q Release Notes 277
VMware ESXi 7.0 Update 3p Release Notes 336
VMware ESXi 7.0 Update 3o Release Notes 366
VMware ESXi 7.0 Update 3n Release Notes 431
VMware ESXi 7.0 Update 3m Release Notes 461
VMware ESXi 7.0 Update 3l Release Notes 491
ESXi Release Notes Before Mar'23 546
vCenter Server Update and Patch Releases **634**
VMware vCenter Server 7.0 Update 3w Release Notes 634
VMware vCenter Server 7.0 Update 3v Release Notes 662
VMware vCenter Server 7.0 Update 3u Release Notes 694
VMware vCenter Server 7.0 Update 3t Release Notes 722
VMware vCenter Server 7.0 Update 3s Release Notes 724
VMware vCenter Server 7.0 Update 3r Release Notes 752
VMware vCenter Server 7.0 Update 3q Release Notes 781
VMware vCenter Server 7.0 Update 3p Release Notes 819
VMware vCenter Server 7.0 Update 3o Release Notes 847
VMware vCenter Server 7.0 Update 3n Release Notes 882
VMware vCenter Server 7.0 Update 3m Release Notes 910
VMware vCenter Server 7.0 Update 3l Release Notes 938
vCenter Release Notes Before Mar'23 971
VMware Host Client Release Notes **972**
VMware Host Client 1.37.0 Release Notes 972
VMware Host Client 1.34.8 Release Notes 973
VMware Host Client 1.34.4 Release Notes 975
VMware Host Client 1.34.0 Release Notes 976
ESXi Installation and Setup **978**
ESXi Installation and Setup **978**

About VMware ESXi Installation and Setup....978
Introduction to vSphere Installation and Setup....978
Overview of the vSphere Installation and Setup Process....979
About ESXi Evaluation and Licensed Modes....980
Installing and Setting Up ESXi....980
ESXi Requirements....980
ESXi System Storage Overview....980
ESXi Hardware Requirements....983
Supported Remote Management Server Models and Firmware Versions....986
Recommendations for Enhanced ESXi Performance....986
Incoming and Outgoing Firewall Ports for ESXi Hosts....987
Required Free Space for System Logging....988
VMware Host Client System Requirements....988
ESXi Passwords and Account Lockout....988
Preparing for Installing ESXi....990
Download the ESXi Installer....990
Options for Installing ESXi....991
Media Options for Booting the ESXi Installer....992
Using Remote Management Applications....996
Customizing Installations with vSphere ESXi Image Builder....996
Required Information for ESXi Installation....1030
Installing ESXi....1031
Installing ESXi Interactively....1031
Installing or Upgrading Hosts by Using a Script....1033
Overview of the Network Boot Installation Process....1047
Installing ESXi Using vSphere Auto Deploy....1057
Troubleshooting vSphere Auto Deploy....1125
Setting Up ESXi....1130
ESXi Autoconfiguration....1130
About the Direct Console ESXi Interface....1130
Enable ESXi Shell and SSH Access with the Direct Console User Interface....1133
Managing ESXi Remotely....1134
Set the Password for the Administrator Account....1134
Configuring the BIOS Boot Settings....1134
Configuring Network Settings....1135
Storage Behavior....1141
Configuring System Logging....1142
Set the Host Image Profile Acceptance Level....1153
Remove All Custom Packages on ESXi....1154
Modify ESXi Configuration Files....1154

Deactivate Support for Non-ASCII Characters on ESXi....1154
Reset the System Configuration....1155
After You Install and Set Up ESXi....1155
Licensing ESXi Hosts....1155
View System Logs....1156
Troubleshooting ESXi Booting....1157
Host Stops Unexpectedly at Bootup When Sharing a Boot Disk with Another Host....1157
Host Fails to Boot After You Install ESXi in UEFI Mode....1157
Decommission an ESXi Host....1158
ESXi Upgrade....1159
About VMware ESXi Upgrade....1159
vCenter Server Upgrade Options....1159
Overview of the vSphere Upgrade Process....1159
Overview of the ESXi Host Upgrade Process....1160
Upgrading Virtual Machines and VMware Tools....1162
Upgrading ESXi Hosts....1163
ESXi Requirements....1163
ESXi System Storage Overview....1163
ESXi Hardware Requirements....1165
Supported Remote Management Server Models and Firmware Versions....1168
Recommendations for Enhanced ESXi Performance....1168
Incoming and Outgoing Firewall Ports for ESXi Hosts....1169
Required Free Space for System Logging....1170
VMware Host Client System Requirements....1170
ESXi Passwords and Account Lockout....1170
Before Upgrading ESXi Hosts....1172
Upgrading Hosts That Have Third-Party Custom VIBs....1173
Upgrading ESXi Hosts in an Environment With VMware NSX....1173
Media Options for Booting the ESXi Installer....1173
Using Remote Management Applications....1177
Download the ESXi Installer....1177
Storage Device Names and Identifiers....1178
Upgrade Hosts Interactively....1179
Installing or Upgrading Hosts by Using a Script....1180
Enter Boot Options to Run an Installation or Upgrade Script....1180
Boot Options....1181
About Installation and Upgrade Scripts....1182
Install or Upgrade ESXi from a CD or DVD by Using a Script....1192
Install or Upgrade ESXi from a USB Stick by Using a Script....1193
Network Boot the ESXi Installer for a Scripted Installation or Upgrade....1193

Overview of the Network Boot Installation Process 1194
Boot the ESXi Installer by Using PXE and TFTP 1195
Boot the ESXi Installer by Using iPXE and HTTP 1196
Boot the ESXi Installer by Using Native UEFI HTTP 1198
Network Boot Background Information 1200
PXELINUX Configuration Files 1201
Sample DHCP Configurations 1201
Upgrading Hosts by Using ESXCLI Commands 1204
VIBs, Image Profiles, and Software Depots 1205
Understanding Acceptance Levels for VIBs and Hosts 1205
See if ESXi Host Update Requires Maintenance Mode or Reboot 1207
Place a Host in Maintenance Mode 1208
Update a Host with Individual VIBs 1209
Upgrade or Update a Host with Image Profiles 1210
Update ESXi Hosts by Using Zip Files 1212
Remove VIBs from a Host 1212
Add Third-Party Extensions to Hosts with an ESXCLI Command 1213
Perform a Dry Run of an ESXCLI Installation or Upgrade 1213
List the Available VIBs and Profiles After Host Reboot 1214
Display the Image Profile and Acceptance Level of the Host 1214
After You Upgrade ESXi Hosts 1215
About ESXi Evaluation and Licensed Modes 1215
Licensing ESXi Hosts After Upgrade 1215
Run the Secure Boot Validation Script on an Upgraded ESXi Host 1216
Configure Syslog on ESXi Hosts 1216
ESXi Syslog Options 1218
Fine-tune Syslog on ESXi Hosts 1222
Configure Log Filtering on ESXi Hosts 1227
Using vSphere Auto Deploy to Reprovision Hosts 1228
Introduction to vSphere Auto Deploy 1228
Preparing for vSphere Auto Deploy 1230
Prepare Your System for vSphere Auto Deploy 1231
Using vSphere Auto Deploy Cmdlets 1232
Set Up Bulk Licensing 1233
Reprovisioning Hosts 1235
Reprovision Hosts with Simple Reboot Operations 1235
Reprovision a Host with a New Image Profile by Using PowerCLI 1235
Write a Rule and Assign a Host Profile to Hosts 1236
Test and Repair Rule Compliance 1237
Collect Logs to Troubleshoot ESXi Hosts 1238

vCenter Server Installation and Setup....1239

Introduction to vSphere Installation and Setup....1239

Overview of the vSphere Installation and Setup Process....1239

vCenter Server Components and Services....1240

Overview of the vCenter Server Appliance....1242

Understanding vSphere Domains and Domain Names....1242

vCenter Enhanced Linked Mode....1243

vCenter Enhanced Linked Mode for vCenter Server Appliance....1243

Deploying the vCenter Server Appliance....1244

System Requirements for the vCenter Server Appliance....1245

Hardware Requirements for the vCenter Server Appliance....1245

Storage Requirements for the vCenter Server Appliance....1246

Software Requirements for the vCenter Server Appliance....1247

Required Ports for vCenter Server....1247

DNS Requirements for the vCenter Server Appliance....1247

vSphere Client Software Requirements....1248

Preparing for Deployment of the vCenter Server Appliance....1248

System Requirements for the vCenter Server Installer....1248

Download and Mount the vCenter Server Installer....1249

Synchronizing Clocks on the vSphere Network....1250

System Clock Synchronization Between the Client and Server....1250

Prerequisites for Deploying the vCenter Server Appliance....1251

GUI Deployment of the vCenter Server Appliance....1251

Required Information for Deploying a vCenter Server Appliance....1252

Deploy the vCenter Server Appliance by Using the GUI....1255

CLI Deployment of the vCenter Server Appliance....1259

Prepare Your JSON Configuration File for CLI Deployment....1259

Syntax of the CLI Deployment Command....1268

Deploy a vCenter Server Appliance by Using the CLI....1269

Deploy Multiple vCenter Server Appliances Using the CLI....1269

File-Based Backup and Restore of vCenter Server....1270

Considerations and Limitations for File-Based Backup and Restore....1270

Schedule a File-Based Backup....1273

Manually Back up vCenter Server by Using the vCenter Server Management Interface....1274

Restore vCenter Server from a File-Based Backup....1275

Stage 1 - Deploy a New Appliance....1277

Stage 2 - Transfer Data to the Newly Deployed Appliance....1280

Image-Based Backup and Restore of a vCenter Server Environment....1280

Considerations and Limitations for Image-Based Backup and Restore....1280

Restore a vCenter Server Image-based Environment....1283

Restore a vCenter Server Instance....1285
Restore a vCenter Enhanced Linked Mode Environment....1285
After You Deploy the vCenter Server Appliance....1285
Log In to vCenter Server by Using the vSphere Client....1286
Repoint vCenter Server to Another vCenter Server in a Different Domain....1286
Repoint a Single vCenter Server Node to an Existing Domain without a Replication Partner....1286
Repoint a vCenter Server Node to an Existing Domain with a Replication Partner....1289
Repoint a vCenter Server Node to a New Domain....1291
Syntax of the Domain Repoint Command....1293
Understanding Tagging and Authorization Conflicts....1294
vCenter Server Domain Repoint License Considerations....1297
Troubleshooting vCenter Server Installation or Deployment....1297
Collecting Logs for Troubleshooting a vCenter Server Installation or Upgrade....1297
Retrieve Installation Logs Manually....1297
Collect Deployment Log Files for the vCenter Server Appliance....1298
Export a vCenter Server Support Bundle for Troubleshooting....1298
vCenter Server Upgrade....1300
vCenter Server Upgrade Options....1300
Overview of the vSphere Upgrade Process....1300
Overview of the vCenter Server Upgrade Process....1301
vCenter Server Upgrade Compatibility....1303
vCenter Server7.0 Component Behavior Changes That Affect Upgrade....1304
Removal of Platform Services Controller....1305
Upgrade or Migration for vCenter Server Instances with an External Platform Services Controller....1305
Upgrading or Migrating to vSphere License Service....1306
Upgrading the Trust Authority vCenter Server....1306
Differences Between vSphere Upgrades, Patches, Updates, and Migrations....1306
Support for Upgrading a vCenter Server with Multi-Homing....1307
Support for Federal Information Processing Standard 140-2....1307
Support for Transport Security Layer 1.2....1307
Moving from a Deprecated to a Supported vCenter Server Deployment Topology Before Upgrade or Migration....1308
Example Upgrade Paths from vCenter Server 6.5 and 6.7 to vCenter Server7.0....1309
Example Migration Paths from vCenter Server for Windows to vCenter Server 7.0....1310
Upgrading the vCenter Server Appliance....1312
About the Upgrade Process of the vCenter Server Appliance....1313
System Requirements for the vCenter Server Appliance....1314
Hardware Requirements for the vCenter Server Appliance....1314
Storage Requirements for the vCenter Server Appliance....1314
Software Requirements for the vCenter Server Appliance....1315

Required Ports for vCenter Server....1315
DNS Requirements for the vCenter Server Appliance....1316
vSphere Client Software Requirements....1316
Preparing to Upgrade the vCenter Server Appliance....1317
System Requirements for the vCenter Server Installer....1317
Download and Mount the vCenter Server Installer....1318
Synchronizing Clocks on the vSphere Network....1318
Transferring Data After Upgrade or Migration....1319
Prepare ESXi Hosts for vCenter Server Appliance Upgrade....1320
Determine the Oracle Database Size and the Storage Size for the New Appliance....1322
Download and Run VMware Migration Assistant on the Source Update Manager Machine....1324
Prerequisites for Upgrading the vCenter Server Appliance....1324
GUI Upgrade of the vCenter Server Appliance....1326
Required Information for Upgrading a vCenter Server Appliance 6.5 or 6.7....1327
Upgrade a vCenter Server Appliance 6.5 or 6.7 with an Embedded Platform Services Controller by Using the GUI....1331
Upgrade a vCenter Server Appliance 6.5 or 6.7 with an External Platform Services Controller Instance by Using the GUI....1337
Upgrading vCenter Server in High Availability Environments....1342
Prerequisites for Upgrading vCenter Server High Availability Environments....1342
Upgrade a vCenter Server Appliance 6.5 or 6.7 HA Cluster with an Embedded Platform Services Controller by Using the GUI....1343
Upgrade a vCenter 6.5 or 6.7 HA Cluster with an External Platform Services Controller by Using the GUI. 1347
CLI Upgrade of the vCenter Server Appliance....1353
Prepare Your JSON Configuration File for CLI Upgrade....1353
Upgrade a vCenter Server Appliance by Using the CLI....1365
Syntax of the CLI Upgrade Command....1366
Migrating vCenter Server for Windows to Appliance....1368
Overview of Migration from vCenter Server on Windows to vCenter Server Appliance....1368
Migration of Update Manager from Windows to a vCenter Server Appliance 7.0....1370
System Requirements for Migrating vCenter Server Deployments to Appliance Deployments....1370
Pre-migration Checks....1371
Known Limitations....1372
Preparing for Migration....1372
Synchronizing Clocks on the vSphere Network....1372
Preparing vCenter Server Databases for Migration....1373
Prepare Managed ESXi Hosts for Migration....1375
Preparing vCenter Server Certificates for Migration....1376
System Requirements for the vCenter Server Installer....1377
Determine the Oracle Database Size and the Storage Size for the New Appliance....1377

Determine the Microsoft SQL Server Database Size and the Storage Size for the New vCenter Server Appliance....1379
Download and Run VMware Migration Assistant on the Source Windows Machine....1380
Prerequisites for Migrating vCenter Server....1381
Required Information for Migrating vCenter Server from Windows to an Appliance....1383
GUI Migration of vCenter Server with an Embedded Platform Services Controller to an vCenter Server Appliance....1386
Deploy the OVA File for Migrating to the Target vCenter Server Appliance....1387
Set Up the Target vCenter Server Appliance....1391
GUI Migration of vCenter Server with an External Platform Services Controller to an Appliance....1391
Deploy the OVA File for the Target vCenter Server Appliance....1393
Set Up the Target vCenter Server Appliance....1396
CLI Migration of a vCenter Server Installation from Windows to an Appliance....1397
Prepare JSON Configuration Files for CLI Migration....1397
JSON Templates for CLI Migration of vCenter Server for Windows....1398
About Migrating a vCenter Server for Windows with an External Platform Services Controller Using the CLI....1399
Migration Configuration Parameters....1401
Run a Pre-Check Before a CLI Migration to vCenter Server Appliance....1409
Perform a CLI Migration of vCenter Server from Windows to an Appliance....1410
Syntax of the CLI Migrate Command....1411
After Upgrading or Migrating vCenter Server....1412
Verify Your vCenter Server Upgrade or Migration Is Successful....1413
Log In to vCenter Server by Using the vSphere Client....1413
Decommission the Platform Services Controller....1414
Decommission an External Platform Services Controller Appliance....1414
Decommission an External Platform Server Controller for Windows....1415
Identity Sources for vCenter Server with vCenter Single Sign-On....1415
Reregister Plug-In Solution in vCenter Server After Upgrade or Migration....1416
Roll Back a vCenter Server Upgrade or vCenter Server on Windows Migration....1416
Monitor and Manage Historical Data Migration....1416
Managing Software Updates, Upgrades, and Product Compatibility....1417
Monitor Interoperability for the Current vCenter Server Version....1418
Generate an Interoperability Report for Target vCenter Server Versions....1418
Generate Pre-Update Reports....1419
Patching and Updating vCenter Server7.0 Deployments....1419
Patching vCenter Server....1420
Patching vCenter Server Using the vCenter Server Management Interface....1420
Patching the vCenter Server Appliance by Using the Appliance Shell....1424
Patch a vCenter High Availability Environment....1428

Troubleshooting a vSphere Upgrade **1429**
Collect Installation Logs for vCenter Server Appliance 1429
Errors and Warnings Returned by the Installation and Upgrade Precheck Script 1429
Upgrade Issues with vCenter Server Containing Host Profiles 1431
Roll Back a vCenter Server Instance on Windows When vCenter Server Upgrade Fails 1432
Collect Logs to Troubleshoot ESXi Hosts 1433
vSphere Authentication **1434**
Updated Information **1435**
Getting Started with Certificate Management and Authentication **1436**
vSphere Certificate Management and Authentication Overview 1437
Managing Certificates 1438
Manage Certificates from the vSphere Client 1438
Use Scripts to Manage Certificates 1439
Managing Authentication Services 1439
Manage Authentication Services from the vSphere Client 1440
Use Scripts to Manage Authentication Services 1440
Managing the vCenter Server 1440
Manage vCenter Server with the Management Interface 1441
Manage vCenter Server from the vCenter Server Shell 1441
Add a vCenter Server to an Active Directory Domain 1442
vSphere Security Certificates **1442**
Certificate Requirements for Different Solution Paths 1443
Certificate Management Overview 1446
Certificate Replacement Overview 1448
Where vSphere Uses Certificates 1450
VMCA and VMware Core Identity Services 1452
VMware Endpoint Certificate Store Overview 1452
Managing Certificate Revocation 1454
Certificate Replacement in Large Deployments 1454
Managing Certificates with the vSphere Client 1455
Explore Certificate Stores from the vSphere Client 1456
Set the Threshold for vCenter Certificate Expiration Warnings 1457
Renew VMCA Certificates with New VMCA-Signed Certificates from the vSphere Client 1457
Set Up Your System to Use Custom Certificates 1457
Managing Certificates with the vSphere Certificate Manager Utility 1460
Certificate Manager Options and the Workflows in This Document 1461
Regenerate a New VMCA Root Certificate and Replace All Certificates 1462
Make VMCA an Intermediate Certificate Authority (Certificate Manager) 1463
Replace All Certificates with Custom Certificate (Certificate Manager) 1466
Revert Last Performed Operation by Republishing Old Certificates 1469

Reset All Certificates Using the Certificate Manager 1469
Manual Certificate Replacement 1469
Understanding Stopping and Starting of Services 1469
Replace Existing VMCA-Signed Certificates with New VMCA-Signed Certificates 1470
Use VMCA as an Intermediate Certificate Authority 1476
Use Custom Certificates with vSphere 1483
Managing Services and Certificates with CLI Commands 1486
Required Privileges for Running CLIs 1486
Changing the certool Configuration Options 1487
certool Initialization Commands Reference 1488
certool Management Commands Reference 1490
vecs-cli Command Reference 1493
dir-cli Command Reference 1497
vSphere Authentication with vCenter Single Sign-On 1503
How vCenter Single Sign-On Protects Your Environment 1504
Understanding vCenter Server Identity Provider Federation 1506
How vCenter Server Identity Provider Federation Works 1506
vCenter Server Identity Provider Federation and Enhanced Linked Mode 1507
vCenter Server Identity Provider Federation Caveats and Interoperability 1508
vCenter Server Identity Provider Federation Life Cycle 1510
Configuring vCenter Server Identity Provider Federation 1510
vCenter Server Identity Provider Federation Configuration Process Flow 1510
Use the Trusted Root Certificates Store Instead of the JRE truststore 1512
Configure vCenter Server Identity Provider Federation for AD FS 1512
Understanding vCenter Single Sign-On 1515
vCenter Single Sign-On Components 1515
Using vCenter Single Sign-On with vSphere 1516
Groups in the vCenter Single Sign-On Domain 1516
Configuring vCenter Single Sign-On Identity Sources 1518
Identity Sources for vCenter Server with vCenter Single Sign-On 1518
Set the Default Domain for vCenter Single Sign-On 1519
Add or Edit a vCenter Single Sign-On Identity Source 1519
Use vCenter Single Sign-On with Windows Session Authentication 1523
Managing the vCenter Server Security Token Service 1524
Refresh a vCenter Server STS Certificate Using the vSphere Client 1524
Import and Replace a vCenter Server STS Certificate Using the vSphere Client 1526
Replace a vCenter Server STS Certificate Using the Command Line 1526
View the Active vCenter Server STS Signing Certificate Chain 1527
Determine the Expiration Date of an LDAPS SSL Certificate 1528
Managing vCenter Single Sign-On Policies 1528

Edit the vCenter Single Sign-On Password Policy....1528
Edit the vCenter Single Sign-On Lockout Policy....1530
Edit the vCenter Single Sign-On Token Policy....1530
Edit Password Expiration Notification for Active Directory (Integrated Windows Authentication) Users....1531
Managing vCenter Single Sign-On Users and Groups....1532
Add vCenter Single Sign-On Users....1532
Disable and Enable vCenter Single Sign-On Users....1533
Delete a vCenter Single Sign-On User....1533
Edit a vCenter Single Sign-On User....1534
Add a vCenter Single Sign-On Group....1534
Add Members to a vCenter Single Sign-On Group....1535
Remove Members from a vCenter Single Sign-On Group....1536
Change Your vCenter Single Sign-On Password....1536
Understanding Other Authentication Options....1537
Smart Card Authentication Login....1538
Configuring and Using Smart Card Authentication....1538
Set Up RSA SecurID Authentication....1544
Managing the Login Message to the vSphere Client Login Page....1545
Manage the Login Message to the vSphere Client Login Page....1546
vCenter Single Sign-On Security Best Practices....1546
Troubleshooting Authentication....1547
Determining the Cause of a Lookup Service Error....1547
Unable to Log In Using Active Directory Domain Authentication....1548
vCenter Server Login Fails Because the User Account Is Locked....1549
VMware Directory Service Replication Can Take a Long Time....1549
Export a vCenter Server Support Bundle....1549

Release Notes

Release notes include product enhancements and notices, bug fixes, and resolved issues.

VMware vSphere 7.0 Release Notes

This document contains the following sections

- Introduction
- What's New
- Internationalization
- Compatibility
- Before You Begin
- Installation and Upgrades for This Release
- Open Source Components for vSphere 7.0
- Product Support Notices
- Known Issues

Introduction

ESXi 7.0 | 2 APR 2020 | ISO Build 15843807 vCenter Server 7.0 | 2 APR 2020 | ISO Build 15952498 Check for additions and updates to these release notes.

What's New

- This release of VMware vSphere 7.0 includes VMware ESXi 7.0 and VMware vCenter Server 7.0. Read about the new and enhanced features in this release in What's New in vSphere 7.0.

Internationalization

vSphere 7.0 is available in the following languages:

- English
- French
- German
- Spanish
- Japanese
- Korean
- Simplified Chinese
- Traditional Chinese

Components of vSphere 7.0, including vCenter Server, ESXi, the vSphere Client, and the vSphere Host Client, do not accept non-ASCII input.

Compatibility

ESXi and vCenter Server Version Compatibility

The VMware Product Interoperability Matrix provides details about the compatibility of current and earlier versions of VMware vSphere components, including ESXi, VMware vCenter Server, and optional VMware products. Check the VMware Product Interoperability Matrix also for information about supported management and backup agents before you install ESXi or vCenter Server.

The vSphere Lifecycle Manager and vSphere Client are packaged with vCenter Server.

Hardware Compatibility for ESXi

To view a list of processors, storage devices, SAN arrays, and I/O devices that are compatible with vSphere 7.0, use the ESXi 7.0 information in the VMware Compatibility Guide.

Device Compatibility for ESXi

To determine which devices are compatible with ESXi 7.0, use the ESXi 7.0 information in the VMware Compatibility Guide.

Guest Operating System Compatibility for ESXi

To determine which guest operating systems are compatible with vSphere 7.0, use the ESXi 7.0 information in the VMware Compatibility Guide.

Virtual Machine Compatibility for ESXi

Virtual machines that are compatible with ESX 3.x and later (hardware version 4) are supported with ESXi 7.0. Virtual machines that are compatible with ESX 2.x and later (hardware version 3) are not supported. To use such virtual machines on ESXi 7.0, upgrade the virtual machine compatibility. See the *ESXi Upgrade* documentation.

Before You Begin

vSphere 7.0 requires one CPU license for up to 32 physical cores. If a CPU has more than 32 cores, additional CPU licenses are required as announced in "Update to VMware's per-CPU Pricing Model". Prior to upgrading ESXi hosts, you can determine the number of licenses required using the license counting tool described in "Counting CPU licenses needed under new VMware licensing policy".

Installation and Upgrades for This Release

Installation Notes for This Release

Read the *ESXi Installation and Setup* and the vCenter Server Installation and Setupdocumentation for guidance about installing and configuring ESXi and vCenter Server.

Although the installations are straightforward, several subsequent configuration steps are essential. Read the following documentation:

- "License Management" in the *vCenter Server and Host Management* documentation
- "Networking" in the *vSphere Networking* documentation
- "Security" in the *vSphere Security* documentation for information on firewall ports

VMware's Configuration Maximums tool helps you plan your vSphere deployments. Use this tool to view the limits for virtual machines, ESXi, vCenter Server, vSAN, networking, and so on. You can also compare limits for two or more product releases. The VMware Configuration Maximums tool is best viewed on larger format devices such as desktops and laptops.

VMware Tools Bundling Changes in ESXi 7.0

In ESXi 7.0, a subset of VMware Tools 11.0.5 and VMware Tools 10.3.21 ISO images are bundled with the ESXi 7.0 host.

The following VMware Tools 11.0.5 ISO image is bundled with ESXi:

- windows.iso: VMware Tools image for Windows Vista or higher

The following VMware Tools 10.3.21 ISO image is bundled with ESXi:

- linux.iso: VMware Tools image for Linux OS with glibc 2.5 or higher

The following VMware Tools 11.0.5 ISO images are available for download:

- darwin.iso: VMware Tools image for OSX

Follow the procedures listed in the following documents to download VMware Tools for platforms not bundled with ESXi:

- VMware Tools 11.0.5 Release Notes
- VMware Tools 10.3.21 Release Notes
- VMware Tools Documentation

Migrating Third-Party Solutions

For information about upgrading with third-party customizations, see the *ESXi Upgrade* documentation. For information about using Image Builder to make a custom ISO, see the *ESXi Installation and Setup* documentation.

Upgrades and Installations Disallowed for Unsupported CPUs

Comparing the processors supported by vSphere 6.7, vSphere 7.0 no longer supports the following processors:

- Intel Family 6, Model = 2C (Westmere-EP)
- Intel Family 6, Model = 2F (Westmere-EX)

During an installation or upgrade, the installer checks the compatibility of the host CPU with vSphere 7.0. If your host hardware is not compatible, a purple screen appears with an incompatibility information message, and the vSphere 7.0 installation process stops.

The following CPUs are supported in the vSphere 7.0 release, but they may not be supported in future vSphere releases. Please plan accordingly:

- Intel Family 6, Model = 2A (Sandy Bridge DT/EN, GA 2011)
- Intel Family 6, Model = 2D (Sandy Bridge EP, GA 2012)
- Intel Family 6, Model = 3A (Ivy Bridge DT/EN, GA 2012)
- AMD Family 0x15, Model = 01 (Bulldozer, GA 2012)

Upgrade Notes for This Release

For instructions about upgrading ESXi hosts and vCenter Server, see the *ESXi Upgrade* and the vCenter Server Upgradedocumentation.

Open Source Components for vSphere 7.0

The copyright statements and licenses applicable to the open source software components distributed in vSphere 7.0 are available at http://www.vmware.com. You need to log in to your My VMware account. Then, from the **Downloads** menu, select **vSphere**. On the **Open Source** tab, you can also download the source files for any GPL, LGPL, or other similar licenses that require the source code or modifications to source code to be made available for the most recent available release of vSphere.

Product Support Notices

- VMware vSphere Clients

  In vSphere 7.0, you can take advantage of the features available in the vSphere Client (HTML5). The Flash-based vSphere Web Client has been deprecated and is no longer available. For more information, see Goodbye, vSphere Web Client.

  The VMware Host Client is a web-based application that you can use to manage individual ESXi hosts that are not connected to a vCenter Server system.

- VMware vSphere 7.0 and TLS Protocol

  In vSphere 7.0, TLS 1.2 is enabled by default. TLS 1.0 and TLS 1.1 are disabled by default. If you upgrade vCenter Server to 7.0 and that vCenter Server instance connects to ESXi hosts, other vCenter Server instances, or other services, you might encounter communication problems.

  To resolve this issue, you can use the TLS Configurator utility to enable older versions of the protocol temporarily on 7.0 systems. You can then disable the older less secure versions after all connections use TLS 1.2. For information, see Managing TLS Protocol Configuration with the TLS Configurator Utility.
- Removal of External Platform Services Controller

  In vSphere 7.0, deploying or upgrading vCenter Server in vSphere 7.0 requires the use of vCenter Server appliance, a preconfigured Linux virtual machine optimized for running vCenter Server. The new vCenter Server contains all Platform Services Controller (PSC) services, preserving the functionality and workflows, including authentication, certificate management, and licensing. It is no longer necessary nor possible to deploy and use an external Platform Services Controller. All PSC services have been consolidated into vCenter Server, and deployment and administration have been simplified.
- Removal of vCenter Server for Windows Support

  In vSphere 7.0, vCenter Server for Windows has been removed and support is not available. For more information, see Farewell, vCenter Server for Windows.
- Removal of VNC Server from ESXi

  In vSphere 7.0, the ESXi built-in VNC server has been removed. Users will no longer be able to connect to a virtual machine using a VNC client by setting the **RemoteDisplay.vnc.enable** configure to be true. Instead, users should use the VM Console via the vSphere Client, the ESXi Host Client, or the VMware Remote Console, to connect virtual machines. Customers desiring VNC access to a VM should use the VirtualMachine.AcquireTicket("webmks") API, which offers a VNC-over-websocket connection. The webmks ticket offers authenticated access to the virtual machine console. For more information, please refer to the VMware HTML Console SDK Documentation.
- Deprecation of VMKLinux

  In vSphere 7.0, VMKLinux driver compatibility has been deprecated and removed. vSphere 7.0 will not contain support for VMKLinux APIs and associated VMKLinux drivers. Custom ISO will not be able to have any VMKLinux async drivers. All drivers contained in an ISO must be native drivers. All currently supported devices which are not supported by native drivers will not function and will not be recognized during installation or upgrade. VCG will not show any devices not supported by a native driver as supported in vSphere 7.0.
- Deprecation of 32-bit Userworld Support

  In vSphere 7.0, 32-bit userworld support has been deprecated. Userworlds are the components of ESXi used by partners to provide drivers, plugins, and other system extensions (distributed as VIBs). Userworlds are not customer accessible.

  vSphere 7.0 provides 64-bit userworld support through partner devkits and will retain 32-bit userworld support through this major release. Support for 32-bit userworlds will be permanently removed in the next major ESXi release. To avoid loss of functionality, customers should ensure any vendor-supplied VIBs in use are migrated to 64-bit before upgrading beyond the vSphere 7.0 release.
- Deprecation of Update Manager Plugin

  In vSphere 7.0, the Update Manager plugin used for administering vSphere Update Manager has been replaced with the Lifecycle Manager plugin. Administrative operations for vSphere Update Manager are still available under the Lifecycle Manager plugin, along with new capabilities for vSphere Lifecycle Manager.
- Deprecation of Integrated Windows Authentication

  Integrated Windows Authentication (IWA) is deprecated in vSphere 7.0 and will be removed in a future release. For more information, see VMware Knowledge Base article 78506.
- Deprecation of DCUI Smart Card Authentication

  In a future vSphere release, support for Smart Card Authentication in DCUI will be discontinued. In place of accessing DCUI using Personal Identity Verification (PIV), Common Access Card (CAC), or SC650 smart card, users will be encouraged to perform operations through vCenter, PowerCLI, API calls, or by logging in with a username and password.

- Deprecation of Core Partition Profile in Host Profiles
  In vSphere 7.0, support for Coredump Partitions in Host Profiles has been deprecated. In place of Coredump Partitions, users should transition to Coredump Files.
- Deprecation of Software FCoE Adapters
  Starting from vSphere 7.0, VMware deprecates the configuration of software FCoE adapters that use the native FCoE stack in ESXi and plans to remove the feature in a future vSphere release.
- Vendor add-ons in MyVMware for use with vSphere Lifecycle Manager
  In vSphere 7.0, vendor add-ons are accessible through vCenter Server's vSphere Lifecycle Manager if the vCenter Server instance has been configured to use a proxy or Update Manager Download Service. To access add-ons from MyVMware, navigate to the **Custom ISOs and Add-ons** tab. Under the **OEM Customized Installer CDs and Add-ons**, you can find the custom add-ons from each of the vendors. For more information about vSphere Lifecycle Manager and vendor add-ons, see the Managing Host and Cluster Lifecycle documentation.

Known Issues

Installation, Upgrade, and Migration Issues

- **vmnic and vmhba device names change after an upgrade to ESXi 7.0**

On certain hardware platforms, vmnic and vmhba device names (aliases) might change across an upgrade to ESXi 7.0 from an earlier ESXi version. This occurs on systems whose firmware provides an ACPI _SUN method that returns a physical slot number of 0 for devices that are not in a pluggable slot.

Workaround: You can rename devices by using the instructions in VMware knowledge base article 2091560.

- **The vCenter Upgrade/Migration pre-checks fail with "Unexpected error 87"**

The vCenter Server Upgrade/Migration pre-checks fail when the Security Token Service (STS) certificate does not contain a Subject Alternative Name (SAN) field. This situation occurs when you have replaced the vCenter 5.5 Single Sign-On certificate with a custom certificate that has no SAN field, and you attempt to upgrade to vCenter Server 7.0. The upgrade considers the STS certificate invalid and the pre-checks prevent the upgrade process from continuing.

Workaround: Replace the STS certificate with a valid certificate that contains a SAN field then proceed with the vCenter Server 7.0 Upgrade/Migration.

- **Problems upgrading to vSphere 7.0 with pre-existing CIM providers**

After upgrade, previously installed 32-bit CIM providers stop working because ESXi requires 64-bit CIM providers. Customers may lose management API functions related to CIMPDK, NDDK (native DDK), HEXDK, VAIODK (IO filters), and see errors related to **uwglibc** dependency. The syslog reports module missing, "32 bit shared libraries not loaded."

Workaround: There is no workaround. The fix is to download new 64-bit CIM providers from your vendor.

- **Smart Card and RSA SecurID authentication might stop working after upgrading to vCenter Server 7.0**

If you have configured vCenter Server for either Smart Card or RSA SecurID authentication, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057 before starting the vSphere 7.0 upgrade process. If you do not perform the workaround as described in the KB, you might see the following error messages and Smart Card or RSA SecurID authentication does not work.

"Smart card authentication may stop working. Smart card settings may not be preserved, and smart card authentication may stop working."

or

"RSA SecurID authentication may stop working. RSA SecurID settings may not be preserved, and RSA SecurID authentication may stop working."

Workaround: Before upgrading to vSphere 7.0, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057.

- **Upgrading a vCenter Server with an external Platform Services Controller from 6.7u3 to 7.0 fails with VMAFD error**

When you upgrade a vCenter Server deployment using an external Platform Services Controller, you converge the Platform Services Controller into a vCenter Server appliance. If the upgrade fails with the error install.vmafd.vmdir_vdcpromo_error_21, the VMAFD firstboot process has failed. The VMAFD firstboot process copies the VMware Directory Service Database (data.mdb) from the source Platform Services Controller and replication partner vCenter Server appliance.

Workaround: Disable TCP Segmentation Offload (TSO) and Generic Segmentation Offload (GSO) on the Ethernet adapter of the source Platform Services Controller or replication partner vCenter Server appliance before upgrading a vCenter Server with an external Platform Services Controller. See Knowledge Base article: https://kb.vmware.com/s/article/74678

- **Upgrading vCenter Server using the CLI incorrectly preserves the Transport Security Layer (TLS) configuration for the vSphere Authentication Proxy service**

If the vSphere Authentication Proxy service (vmcam) is configured to use a particular TLS protocol other than the default TLS 1.2 protocol, this configuration is preserved during the CLI upgrade process. By default, vSphere supports the TLS 1.2 encryption protocol. If you must use the TLS 1.0 and TLS 1.1 protocols to support products or services that do not support TLS 1.2, use the TLS Configurator Utility to enable or disable different TLS protocol versions.

Workaround: Use the TLS Configurator Utility to configure the vmcam port. To learn how to manage TLS protocol configuration and use the TLS Configurator Utility, see the *VMware Security* documentation.

- **Smart card and RSA SecurID settings may not be preserved during vCenter Server upgrade**

Authentication using RSA SecurID will not work after upgrading to vCenter Server 7.0. An error message will alert you to this issue when attempting to login using your RSA SecurID login.

Workaround: Reconfigure the smart card or RSA SecureID.

- **Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with network error message**

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with the error message IP already exists in the network. This prevents the migration process from configuring the network parameters on the new vCenter Server appliance. For more information, examine the log file: /var/log/vmware/upgrade/UpgradeRunner.log

Workaround:

- a. Verify that all Windows Updates have been completed on the source vCenter Server for Windows instance, or disable automatic Windows Updates until after the migration finishes.
  b. Retry the migration of vCenter Server for Windows to vCenter Server appliance 7.0.

- **When you configure the number of virtual functions for an SR-IOV device by using the max_vfs module parameter, the changes might not take effect**

In vSphere 7.0, you can configure the number of virtual functions for an SR-IOV device by using the Virtual Infrastructure Management (VIM) API, for example, through the vSphere Client. The task does not require reboot of the ESXi host. After you use the VIM API configuration, if you try to configure the number of SR-IOV virtual functions by using the max_vfs module parameter, the changes might not take effect because they are overridden by the VIM API configuration.

Workaround: None. To configure the number of virtual functions for an SR-IOV device, use the same method every time. Use the VIM API or use the max_vfs module parameter and reboot the ESXi host.

- **Upgraded vCenter Server appliance instance does not retain all the secondary networks (NICs) from the source instance**

During a major upgrade, if the source instance of the vCenter Server appliance is configured with multiple secondary networks other than the VCHA NIC, the target vCenter Server instance will not retain secondary networks other than the VCHA NIC. If the source instance is configured with multiple NICs that are part of DVS port groups, the NIC configuration will not be preserved during the upgrade. Configurations for vCenter Server appliance instances that are part of the standard port group will be preserved.

Workaround: None. Manually configure the secondary network in the target vCenter Server appliance instance.

- **After upgrading or migrating a vCenter Server with an external Platform Services Controller, users authenticating using Active Directory lose access to the newly upgraded vCenter Server instance**

After upgrading or migrating a vCenter Server with an external Platform Services Controller, if the newly upgraded vCenter Server is not joined to an Active Directory domain, users authenticating using Active Directory will lose access to the vCenter Server instance.

Workaround: Verify that the new vCenter Server instance has been joined to an Active Directory domain. See Knowledge Base article: https://kb.vmware.com/s/article/2118543

- **Migrating a vCenter Server for Windows with an external Platform Services Controller using an Oracle database fails**

If there are non-ASCII strings in the Oracle events and tasks table the migration can fail when exporting events and tasks data. The following error message is provided: UnicodeDecodeError

Workaround: None.

- **After an ESXi host upgrade, a Host Profile compliance check shows non-compliant status while host remediation tasks fail**

The non-compliant status indicates an inconsistency between the profile and the host.

This inconsistency might occur because ESXi 7.0 does not allow duplicate claim rules, but the profile you use contains duplicate rules. For example, if you attempt to use the Host Profile that you extracted from the host before upgrading ESXi 6.5 or ESXi 6.7 to version 7.0 and the Host Profile contains any duplicate claim rules of system default rules, you might experience the problems.

Workaround:

- a. Remove any duplicate claim rules of the system default rules from the Host Profile document.
  b. Check the compliance status.
  c. Remediate the host.
  d. If the previous steps do not help, reboot the host.

- **Error message displays in the vCenter Server Management Interface**

After installing or upgrading to vCenter Server 7.0, when you navigate to the Update panel within the vCenter Server Management Interface, the error message "Check the URL and try again" displays. The error message does not prevent you from using the functions within the Update panel, and you can view, stage, and install any available updates.

Workaround: None.

Security Features Issues

- **Encrypted virtual machine fails to power on when HA-enabled Trusted Cluster contains an unattested host**

In VMware® vSphere Trust Authority™, if you have enabled HA on the Trusted Cluster and one or more hosts in the cluster fails attestation, an encrypted virtual machine cannot power on.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

- **Encrypted virtual machine fails to power on when DRS-enabled Trusted Cluster contains an unattested host**

In VMware® vSphere Trust Authority™, if you have enabled DRS on the Trusted Cluster and one or more hosts in the cluster fails attestation, DRS might try to power on an encrypted virtual machine on an unattested host in the cluster. This operation puts the virtual machine in a locked state.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

- **Migrating or cloning encrypted virtual machines across vCenter Server instances fails when attempting to do so using the vSphere Client**

If you try to migrate or clone an encrypted virtual machine across vCenter Server instances using the vSphere Client, the operation fails with the following error message: "The operation is not allowed in the current state."

Workaround: You must use the vSphere APIs to migrate or clone encrypted virtual machines across vCenter Server instances.

Networking Issues

- **Reduced throughput in networking performance on Intel 82599/X540/X550 NICs**

The new queue-pair feature added to ixgben driver to improve networking performance on Intel 82599EB/X540/X550 series NICs might reduce throughput under some workloads in vSphere 7.0 as compared to vSphere 6.7.

Workaround: To achieve the same networking performance as vSphere 6.7, you can disable the queue-pair with a module parameter. To disable the queue-pair, run the command:

esxcli system module parameters set -p "QPair=0,0,0,0..." -m ixgben

After running the command, reboot.

- **High throughput virtual machines may experience degradation in network performance when Network I/O Control (NetIOC) is enabled**

Virtual machines requiring high network throughput can experience throughput degradation when upgrading from vSphere 6.7 to vSphere 7.0 with NetIOC enabled.

Workaround: Adjust the ethernetx.ctxPerDev setting to enable multiple worlds.

- **IPv6 traffic fails to pass through VMkernel ports using IPsec**

When you migrate VMkernel ports from one port group to another, IPv6 traffic does not pass through VMkernel ports using IPsec.

Workaround: Remove the IPsec security association (SA) from the affected server, and then reapply the SA. To learn how to set and remove an IPsec SA, see the *vSphere Security* documentation.

- **Higher ESX network performance with a portion of CPU usage increase**

ESX network performance may increase with a portion of CPU usage.

Workaround: Remove and add the network interface with only 1 rx dispatch queue. For example:

esxcli network ip interface remove --interface-name=vmk1

esxcli network ip interface add --interface-name=vmk1 --num-rxqueue=1

- **VM might lose Ethernet traffic after hot-add, hot-remove or storage vMotion**

A VM might stop receiving Ethernet traffic after a hot-add, hot-remove or storage vMotion. This issue affects VMs where the uplink of the VNIC has SR-IOV enabled. PVRDMA virtual NIC exhibits this issue when the uplink of the virtual network is a Mellanox RDMA capable NIC and RDMA namespaces are configured.

Workaround: You can hot-remove and hot-add the affected Ethernet NICs of the VM to restore traffic. On Linux guest operating systems, restarting the network might also resolve the issue. If these workarounds have no effect, you can reboot the VM to restore network connectivity.

- **Change of IP address for a VCSA deployed with static IP address requires that you create the DNS records in advance**

With the introduction of the DDNS, the DNS record update only works for VCSA deployed with DHCP configured networking. While changing the IP address of the vCenter server via VAMI, the following error is displayed:

The specified IP address does not resolve to the specified hostname.

Workaround: There are two possible workarounds.

- a. Create an additional DNS entry with the same FQDN and desired IP address. Log in to the VAMI and follow the steps to change the IP address.
  b. Log in to the VCSA using ssh. Execute the following script:

./opt/vmware/share/vami/vami_config_net

Use option 6 to change the IP adddress of eth0. Once changed, execute the following script:

./opt/likewise/bin/lw-update-dns

Restart all the services on the VCSA to update the IP information on the DNS server.

- **It may take several seconds for the NSX Distributed Virtual Port Group (NSX DVPG) to be removed after deleting the corresponding logical switch in NSX Manager.**

As the number of logical switches increases, it may take more time for the NSX DVPG in vCenter Server to be removed after deleting the corresponding logical switch in NSX Manager. In an environment with 12000 logical switches, it takes approximately 10 seconds for an NSX DVPG to be deleted from vCenter Server.

Workaround: None.

- **Hostd runs out of memory and fails if a large number of NSX Distributed Virtual port groups are created.**

In vSphere 7.0, NSX Distributed Virtual port groups consume significantly larger amounts of memory than opaque networks. For this reason, NSX Distributed Virtual port groups can not support the same scale as an opaque network given the same amount of memory.

Workaround:To support the use of NSX Distributed Virtual port groups, increase the amount of memory in your ESXi hosts. If you verify that your system has adequate memory to support your VMs, you can directly increase the memory of hostd using the following command.

localcli --plugin-dir /usr/lib/vmware/esxcli/int/ sched group setmemconfig --group-path host/vim/vmvisor/hostd --units mb --min 2048 --max 2048

Note that this will cause hostd to use memory normally reserved for your environment's VMs. This may have the affect of reducing the number of VMs your ESXi host can support.

- **DRS may incorrectly launch vMotion if the network reservation is configured on a VM**

If the network reservation is configured on a VM, it is expected that DRS only migrates the VM to a host that meets the specified requirements. In a cluster with NSX transport nodes, if some of the transport nodes join the transport zone by NSX-T Virtual Distributed Switch (N-VDS), and others by vSphere Distributed Switch (VDS) 7.0, DRS may incorrectly launch vMotion. You might encounter this issue when:

- – The VM connects to an NSX logical switch configured with a network reservation.
  – Some transport nodes join transport zone using N-VDS, and others by VDS 7.0, or, transport nodes join the transport zone through different VDS 7.0 instances.

Workaround: Make all transport nodes join the transport zone by N-VDS or the same VDS 7.0 instance.

- **When adding a VMkernel NIC (vmknic) to an NSX portgroup, vCenter Server reports the error "Connecting VMKernel adapter to a NSX Portgroup on a Stateless host is not a supported operation. Please use Distributed Port Group instead."**

- – For stateless ESXi on Distributed Virtual Switch (DVS), the vmknic on a NSX port group is blocked. You must instead use a Distributed Port Group.
  – For stateful ESXi on DVS, vmknic on NSX port group is supported, but vSAN may have an issue if it is using vmknic on a NSX port group.

Workaround: Use a Distributed Port Group on the same DVS.

- **Enabling SRIOV from vCenter for QLogic 4x10GE QL41164HFCU CNA might fail**

If you navigate to the **Edit Settings** dialog for physical network adapters and attempt to enable SR-IOV, the operation might fail when using QLogic 4x10GE QL41164HFCU CNA. Attempting to enable SR-IOV might lead to a network outage of the ESXi host.

Workaround: Use the following command on the ESXi host to enable SRIOV:

esxcfg-module

- **New vCenter Server fails if the hosts in a cluster using Distributed Resource Scheduler (DRS) join NSX-T networking by a different Virtual Distributed Switch (VDS) or combination of NSX-T Virtual Distributed Switch (NVDS) and VDS**

In vSphere 7.0, when using NSX-T networking on vSphere VDS with a DRS cluster, if the hosts do not join the NSX transport zone by the same VDS or NVDS, it can cause vCenter Server to fail.

Workaround: Have hosts in a DRS cluster join the NSX transport zone using the same VDS or NVDS.

Storage Issues

- **VMFS datastores are not mounted automatically after disk hot remove and hot insert on HPE Gen10 servers with SmartPQI controllers**

When SATA disks on HPE Gen10 servers with SmartPQI controllers without expanders are hot removed and hot inserted back to a different disk bay of the same machine, or when multiple disks are hot removed and hot inserted back in a different order, sometimes a new local name is assigned to the disk. The VMFS datastore on that disk appears as a snapshot and will not be mounted back automatically because the device name has changed.

Workaround: None. SmartPQI controller does not support unordered hot remove and hot insert operations.

- **Setting the loglevel for nvme_pcie driver fails with an error**

When you set the loglevel for nvme_pcie driver with the command esxcli nvme driver loglevel set -l <*log level*>, the action fails with the error message:

Failed to set log level 0x2.

This command was retained for compatibility consideration with NVMe driver, but it is not supported for nvme_pcie driver.

Workaround: None. This condition will exist when the nvme_pcie feature is enabled.

- **ESXi might terminate I/O to NVMeOF devices due to errors on all active paths**

Occasionally, all active paths to NVMeOF device register I/O errors due to link issues or controller state. If the status of one of the paths changes to Dead, the High Performance Plug-in (HPP) might not select another path if it shows high volume of errors. As a result, the I/O fails.

Workaround: Disable the configuration option **/Misc/HppManageDegradedPaths** to unblock the I/O.

- **VOMA check on NVMe based VMFS datastores fails with error**

VOMA check is not supported for NVMe based VMFS datastores and will fail with the error:

ERROR: Failed to reserve device. Function not implemented

Example:

voma -m vmfs -f check -d /vmfs/devices/disks/: <partition#>

Running VMFS Checker version 2.1 in check mode

Initializing LVM metadata, Basic Checks will be done

Checking for filesystem activity

Performing filesystem liveness check..|Scanning for VMFS-6 host activity (4096 bytes/HB, 1024 HBs).

ERROR: Failed to reserve device. Function not implemented

Aborting VMFS volume check

VOMA failed to check device : General Error

Workaround: None. If you need to analyse VMFS metadata, collect it using the -l option, and pass to VMware customer support. The command for collecting the dump is:

voma -l -f dump -d /vmfs/devices/disks/:<partition#>

- **Using the VM reconfigure API to attach an encrypted First Class Disk to an encrypted virtual machine might fail with error**

If an FCD and a VM are encrypted with different crypto keys, your attempts to attach the encrypted FCD to the encrypted VM using the VM reconfigure API might fail with the error message:

Cannot decrypt disk because key or password is incorrect.

Workaround: Use the attachDisk API rather than the VM reconfigure API to attach an encrypted FCD to an encrypted VM.

- **ESXi host might get in non responding state if a non-head extent of its spanned VMFS datastore enters the Permanent Device Loss (PDL) state**

This problem does not occur when a non-head extent of the spanned VMFS datastore fails along with the head extent. In this case, the entire datastore becomes inaccessible and no longer allows I/Os.

In contrast, when only a non-head extent fails, but the head extent remains accessible, the datastore heartbeat appears to be normal. And the I/Os between the host and the datastore continue. However, any I/Os that depend on the failed non-head extent start failing as well. Other I/O transactions might accumulate while waiting for the failing I/Os to resolve, and cause the host to enter the non responding state.

Workaround: Fix the PDL condition of the non-head extent to resolve this issue.

- **After recovering from APD or PDL conditions, VMFS datastore with enabled support for clustered virtual disks might remain inaccessible**

You can encounter this problem only on datastores where the clustered virtual disk support is enabled. When the datastore recovers from an All Paths Down (APD) or Permanent Device Loss (PDL) condition, it remains inaccessible. The VMkernel log might show multiple SCSI3 reservation conflict messages similar to the following:

2020-02-18T07:41:10.273Z cpu22:1001391219)ScsiDeviceIO: vm 1001391219: SCSIDeviceCmdCompleteCB:2972: Reservation conflict retries 544 for command 0x45ba814b8340 (op: 0x89) to device "naa.624a9370b97601e346f64ba900024d53"

The problem can occur because the ESXi host participating in the cluster loses SCSI reservations for the datastore and cannot always reacquire them automatically after the datastore recovers.

Workaround: Manually register the reservation using the following command:

vmkfstools -L registerkey /vmfs/devices/disks/<device name>

where the <device name> is the name of the device on which the datastore is created.

- **Virtual NVMe Controller is the default disk controller for Windows 10 guest operating systems**

The Virtual NVMe Controller is the default disk controller for the following guest operating systems when using Hardware Version 15 or later:

Windows 10 Windows Server 2016 Windows Server 2019

Some features might not be available when using a Virtual NVMe Controller. For more information, see https://kb.vmware.com/s/article/2147714

Note: Some clients use the previous default of LSI Logic SAS. This includes ESXi host client and PowerCLI.

Workaround: If you need features not available on Virtual NVMe, switch to VMware Paravirtual SCSI (PVSCSI) or LSI Logic SAS. For information on using VMware Paravirtual SCSI (PVSCSI), see https://kb.vmware.com/s/article/1010398

- **After an ESXi host upgrade to vSphere 7.0, presence of duplicate core claim rules might cause unexpected behavior**

Claim rules determine which multipathing plugin, such as NMP, HPP, and so on, owns paths to a particular storage device. ESXi 7.0 does not support duplicate claim rules. However, the ESXi 7.0 host does not alert you if you add duplicate rules to the existing claim rules inherited through an upgrade from a legacy release. As a result of using duplicate rules, storage devices might be claimed by unintended plugins, which can cause unexpected outcome.

Workaround: Do not use duplicate core claim rules. Before adding a new claim rule, delete any existing matching claim rule.

- **A CNS query with the compliance status filter set might take unusually long time to complete**

The CNS QueryVolume API enables you to obtain information about the CNS volumes, such as volume health and compliance status. When you check the compliance status of individual volumes, the results are obtained quickly. However, when you invoke the CNS QueryVolume API to check the compliance status of multiple volumes, several tens or hundreds, the query might perform slowly.

Workaround: Avoid using bulk queries. When you need to get compliance status, query one volume at a time or limit the number of volumes in the query API to 20 or fewer. While using the query, avoid running other CNS operations to get the best performance.

- **New Deleted CNS volumes might temporarily appear as existing in the CNS UI**

After you delete an FCD disk that backs a CNS volume, the volume might still show up as existing in the CNS UI. However, your attempts to delete the volume fail. You might see an error message similar to the following: The object or item referred to could not be found.

Workaround: The next full synchronization will resolve the inconsistency and correctly update the CNS UI.

- **New Attempts to attach multiple CNS volumes to the same pod might occasionally fail with an error**

When you attach multiple volumes to the same pod simultaneously, the attach operation might occasionally choose the same controller slot. As a result, only one of the operations succeeds, while other volume mounts fail.

Workaround: After Kubernetes retries the failed operation, the operation succeeds if a controller slot is available on the node VM.

- **New Under certain circumstances, while a CNS operation fails, the task status appears as successful in the vSphere Client**

This might occur when, for example, you use an incompliant storage policy to create a CNS volume. The operation fails, while the vSphere Client shows the task status as successful.

Workaround: The successful task status in the vSphere Client does not guarantee that the CNS operation succeeded. To make sure the operation succeeded, verify its results.

- **New Unsuccessful delete operation for a CNS persistent volume might leave the volume undeleted on the vSphere datastore**

This issue might occur when the CNS Delete API attempts to delete a persistent volume that is still attached to a pod. For example, when you delete the Kubernetes namespace where the pod runs. As a result, the volume gets cleared from CNS and the CNS query operation does not return the volume. However, the volume continues to reside on the datastore and cannot be deleted through the repeated CNS Delete API operations.

Workaround: None.

vCenter Server and vSphere Client Issues

- **Vendor providers go offline after a PNID change**

When you change the vCenter IP address (PNID change), the registered vendor providers go offline.

Workaround: Re-register the vendor providers.

- **Cross vCenter migration of a virtual machine fails with an error**

When you use cross vCenter vMotion to move a VM's storage and host to a different vCenter server instance, you might receive the error The operation is not allowed in the current state.

This error appears in the UI wizard after the Host Selection step and before the Datastore Selection step, in cases where the VM has an assigned storage policy containing host-based rules such as encryption or any other IO filter rule.

Workaround: Assign the VM and its disks to a storage policy without host-based rules. You might need to decrypt the VM if the source VM is encrypted. Then retry the cross vCenter vMotion action.

- **Storage Sensors information in Hardware Health tab shows incorrect values on vCenter UI, host UI, and MOB**

When you navigate to **Host > Monitor > Hardware Health > Storage Sensors** on vCenter UI, the storage information displays either incorrect or unknown values. The same issue is observed on the host UI and the MOB path “runtime.hardwareStatusInfo.storageStatusInfo” as well.

Workaround: None.

- **vSphere UI host advanced settings shows the current product locker location as empty with an empty default**

vSphere UI host advanced settings shows the current product locker location as empty with an empty default. This is inconsistent as the actual product location symlink is created and valid. This causes confusion to the user. The default cannot be corrected from UI.

Workaround: User can use the esxcli command on the host to correct the current product locker location default as below.

1. Remove the existing Product Locker Location setting with: "esxcli system settings advanced remove -o ProductLockerLocation"

2. Re-add the Product Locker Location setting with the appropriate default:

2.a. If the ESXi is a full installation, the default value is "/locker/packages/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/locker/packages/vmtoolsRepo"

2.b. If the ESXi is a PXEboot configuration such as autodeploy, the default value is: "/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/vmtoolsRepo"

Run the following command to automatically figure out the location: export PRODUCT_LOCKER_DEFAULT=`readlink /productLocker`

Add the setting: esxcli system settings advanced add -d "Path to VMware Tools repository" -o ProductLockerLocation -t string -s $PRODUCT_LOCKER_DEFAULT

You can combine all the above steps in step 2 by issuing the single command:

esxcli system settings advanced add -d "Path to VMware Tools repository" -o ProductLockerLocation -t string -s `readlink /productLocker`

- **Linked Software-Defined Data Center (SDDC) vCenter Server instances appear in the on-premises vSphere Client if a vCenter Cloud Gateway is linked to the SDDC.**

When a vCenter Cloud Gateway is deployed in the same environment as an on-premises vCenter Server, and linked to an SDDC, the SDDC vCenter Server will appear in the on-premises vSphere Client. This is unexpected behavior and the linked SDDC vCenter Server should be ignored. All operations involving the linked SDDC vCenter Server should be performed on the vSphere Client running within the vCenter Cloud Gateway.

Workaround: None.

Virtual Machine Management Issues

- **The postcustomization section of the customization script runs before the guest customization**

When you run the guest customization script for a Linux guest operating system, the precustomization section of the customization script that is defined in the customization specification runs before the guest customization and the postcustomization section runs after that. If you enable Cloud-Init in the guest operating system of a virtual machine, the postcustomization section runs before the customization due to a known issue in Cloud-Init.

Workaround: Disable Cloud-Init and use the standard guest customization.

- **Group migration operations in vSphere vMotion, Storage vMotion, and vMotion without shared storage fail with error**

When you perform group migration operations on VMs with multiple disks and multi-level snapshots, the operations might fail with the error com.vmware.vc.GenericVmConfigFault Failed waiting for data. Error 195887167. Connection closed by remote host, possibly due to timeout.

Workaround: Retry the migration operation on the failed VMs one at a time.

- **Deploying an OVF or OVA template from a URL fails with a 403 Forbidden error**

The URLs that contain an HTTP query parameter are not supported. For example, http://webaddress.com?file=abc.ovf or the Amazon pre-signed S3 URLs.

Workaround: Download the files and deploy them from your local file system.

- **Importing or deploying local OVF files containing non-ASCII characters in their name might fail with an error**

When you import local .ovf files containing non-ASCII characters in their name, you might receive 400 Bad Request Error. When you use such .ovf files to deploy a virtual machine in the vSphere Client, the deployment process stops at 0%. As a result, you might receive 400 Bad Request Error or 500 Internal Server Error.

Workaround:

- a. Remove the non-ASCII characters from the .ovf and .vmdk file names.
    - To edit the .ovf file, open it with a text editor.
    - Search the non-ASCII .vmdk file name and change it to ASCII.
  b. Import or deploy the saved files again.
- **New The third level of nested objects in a virtual machine folder is not visible**

Perform the following steps:

- a. Navigate to a data center and create a virtual machine folder.
  b. In the virtual machine folder, create a nested virtual machine folder.
  c. In the second folder, create another nested virtual machine, virtual machine folder, vApp, or VM Template.

As a result, from the VMs and Templates inventory tree you cannot see the objects in the third nested folder.

Workaround: To see the objects in the third nested folder, navigate to the second nested folder and select the VMs tab.

vSphere HA and Fault Tolerance Issues

- **Modified VMs in a cluster might be orphaned after recovering from storage inaccessibility such as a cluster wide APD**

Some VMs might be in orphaned state after cluster wide APD recovers, even if HA and VMCP are enabled on the cluster.

This issue might be encountered when the following conditions occur simultaneously:

- – All hosts in the cluster experience APD and do not recover until VMCP timeout is reached.
  – HA primary initiates failover due to APD on a host.
  – Power on API during HA failover fails due to one of the following:
    - APD across the same host
    - Cascading APD across the entire cluster
    - Storage issues
    - Resource unavailability
  – FDM unregistration and VCs steal VM logic might initiate during a window where FDM has not unregistered the failed VM and VC's host synchronization responds that multiple hosts are reporting the same VM. Both FDM and VC unregister the different registered copies of the same VM from different hosts, causing the VM to be orphaned.

Workaround: You must unregister and reregister the orphaned VMs manually within the cluster after the APD recovers.

If you do not manually reregister the orphaned VMs, HA attempts failover of the orphaned VMs, but it might take between 5 to 10 hours depending on when APD recovers.

The overall functionality of the cluster is not affected in these cases and HA will continue to protect the VMs. This is an anomaly in what gets displayed on VC for the duration of the problem.

vSphere Lifecycle Manager Issues

- **You cannot enable NSX-T on a cluster that is already enabled for managing image setup and updates on all hosts collectively**

NSX-T is not compatible with the vSphere Lifecycle Manager functionality for image management. When you enable a cluster for image setup and updates on all hosts in the cluster collectively, you cannot enable NSX-T on that cluster. However, you can deploy NSX Edges to this cluster.

Workaround: Move the hosts to a new cluster that you can manage with baselines and enable NSX-T on that new cluster.

- **vSphere Lifecycle Manager and vSAN File Services cannot be simultaneously enabled on a vSAN cluster in vSphere 7.0 release**

If vSphere Lifecycle Manager is enabled on a cluster, vSAN File Services cannot be enabled on the same cluster and vice versa. In order to enable vSphere Lifecycle Manager on a cluster, which has VSAN File Services enabled already, first disable vSAN File Services and retry the operation. Please note that if you transition to a cluster that is managed by a single image, vSphere Lifecycle Manager cannot be disabled on that cluster.

Workaround: None.

- **ESXi 7.0 hosts cannot be added to a cluster that you manage with a single image by using vSphere Auto Deploy**

Attempting to add ESXi hosts to a cluster that you manage with a single image by using the "Add to Inventory" workflow in vSphere Auto Deploy fails. The failure occurs because no patterns are matched in an existing Auto Deploy ruleset. The task fails silently and the hosts remain in the Discovered Hosts tab.

Workaround:

- a. Remove the ESXi hosts that did not match the ruleset from the Discovered Hosts tab.
  b. Create a rule or edit an existing Auto Deploy rule, where the host target location is a cluster managed by an image.
  c. Reboot the hosts.

The hosts are added to the cluster that you manage by an image in vSphere Lifecycle Manager.

- **When a hardware support manager is unavailable, vSphere High Availability (HA) functionality is impacted**

If hardware support manager is unavailable for a cluster that you manage with a single image, where a firmware and drivers addon is selected and vSphere HA is enabled, the vSphere HA functionality is impacted. You may experience the following errors.

- – Configuring vSphere HA on a cluster fails.
  – Cannot complete the configuration of the vSphere HA agent on a host: Applying HA VIBs on the cluster encountered a failure.
  – Remediating vSphere HA fails: A general system error occurred: Failed to get Effective Component map.
  – Disabling vSphere HA fails: Delete Solution task failed. A general system error occurred: Cannot find hardware support package from depot or hardware support manager.

Workaround:

- – If the hardware support manager is temporarily unavailable, perform the following steps.
- a. Reconnect the hardware support manager to vCenter Server.
  b. Select a cluster from the Hosts and Cluster menu.
  c. Select the Configure tab.
  d. Under Services, click vSphere Availability.
  e. Re-enable vSphere HA.
- – If the hardware support manager is permanently unavailable, perform the following steps.
- a. Remove the hardware support manager and the hardware support package from the image specification
  b. Re-enable vSphere HA.
  c. Select a cluster from the Hosts and Cluster menu.
  d. Select the Updates tab.
  e. Click Edit .
  f. Remove the firmware and drivers addon and click Save.
  g. Select the Configure tab.
  h. Under Services, click vSphere Availability.
  i. Re-enable vSphere HA.

- **I/OFilter is not removed from a cluster after a remediation process in vSphere Lifecycle Manager**

Removing I/OFilter from a cluster by remediating the cluster in vSphere Lifecycle Manager, fails with the following error message: iofilter XXX already exists. The iofilter remains listed as installed.

Workaround:

- a. Call IOFilter API UninstallIoFilter_Task from the vCenter Server managed object (IoFilterManager).
  b. Remediate the cluster in vSphere Lifecycle Manager.
  c. Call IOFilter API ResolveInstallationErrorsOnCluster_Task from the vCenter Server managed object (IoFilterManager) to update the database.

- **While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, adding hosts causes a vSphere HA error state**

Adding one or multiple ESXi hosts during a remediation process of a vSphere HA enabled cluster, results in the following error message: Applying HA VIBs on the cluster encountered a failure.

Workaround: After the cluster remediation operation has finished, perform one of the following tasks.

- – Right-click the failed ESXi host and select *Reconfigure for vSphere HA*.
  – Disable and re-enable vSphere HA for the cluster.

- **While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, disabling and re-enabling vSphere HA causes a vSphere HA error state**

Disabling and re-enabling vSphere HA during remediation process of a cluster, may fail the remediation process due to vSphere HA health checks reporting that hosts don't have vSphere HA VIBs installed. You may see the following error message: Setting desired image spec for cluster failed.

Workaround: After the cluster remediation operation has finished, disable and re-enable vSphere HA for the cluster.

- **Checking for recommended images in vSphere Lifecycle Manager has slow performance in large clusters**

In large clusters with more than 16 hosts, the recommendation generation task could take more than an hour to finish or may appear to hang. The completion time for the recommendation task depends on the number of devices configured on each host and the number of image candidates from the depot that vSphere Lifecycle Manager needs to process before obtaining a valid image to recommend.

Workaround: None.

- **Checking for hardware compatibility in vSphere Lifecycle Manager has slow performance in large clusters**

In large clusters with more than 16 hosts, the validation report generation task could take up to 30 minutes to finish or may appear to hang. The completion time depends on the number of devices configured on each host and the number of hosts configured in the cluster.

Workaround: None

- **Incomplete error messages in non-English languages are displayed, when remediating a cluster in vSphere Lifecycle Manager**

You can encounter incomplete error messages for localized languages in the vCenter Server user interface. The messages are displayed, after a cluster remediation process in vSphere Lifecycle Manager fails. For example, your can observe the following error message. The error message in English language: Virtual machine 'VMC on DELL EMC - FileServer' that runs on cluster 'Cluster-1' reported an issue which prevents entering maintenance mode: Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx The error message in French language: La VM « VMC on DELL EMC -FileServer », située sur le cluster « {Cluster-1} », a signalé un problème empêchant le passage en mode de maintenance : Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx

Workaround: None.

- **Importing an image with no vendor addon, components, or firmware and drivers addon to a cluster which image contains such elements, does not remove the image elements of the existing image**

Only the ESXi base image is replaced with the one from the imported image.

Workaround: After the import process finishes, edit the image, and if needed, remove the vendor addon, components, and firmware and drivers addon.

- **When you convert a cluster that uses baselines to a cluster that uses a single image, a warning is displayed that vSphere HA VIBs will be removed**

Converting a vSphere HA enabled cluster that uses baselines to a cluster that uses a single image, may result a warning message displaying that vmware-fdm component will be removed.

Workaround: This message can be ignored. The conversion process installs the vmware-fdm component.

- **If vSphere Update Manager is configured to download patch updates from the Internet through a proxy server, after upgrade to vSphere 7.0 that converts Update Manager to vSphere Lifecycle Manager, downloading patches from VMware patch repository might fail**

In earlier releases of vCenter Server you could configure independent proxy settings for vCenter Server and vSphere Update Manager. After an upgrade to vSphere 7.0, vSphere Update Manager service becomes part of the vSphere Lifecycle Manager service. For the vSphere Lifecycle Manager service, the proxy settings are configured from the vCenter Server appliance settings. If you had configured Update Manager to download patch updates from the Internet through a proxy server but the vCenter Server appliance had no proxy setting configuration, after a vCenter Server upgrade to version 7.0, the vSphere Lifecycle Manager fails to connect to the VMware depot and is unable to download patches or updates.

Workaround: Log in to the vCenter Server Appliance Management Interface, https://*vcenter-server-appliance-FQDN-or-IP-address*:5480, to configure proxy settings for the vCenter Server appliance and enable vSphere Lifecycle Manager to use proxy.

Miscellaneous Issues

- **When applying a host profile with version 6.5 to a ESXi host with version 7.0, the compliance check fails**

Applying a host profile with version 6.5 to a ESXi host with version 7.0, results in Coredump file profile reported as not compliant with the host.

Workaround: There are two possible workarounds.

- a. When you create a host profile with version 6.5, set an advanced configuration option VMkernel.Boot.autoCreateDumpFile to false on the ESXi host.
  b. When you apply an existing host profile with version 6.5, add an advanced configuration option VMkernel.Boot.autoCreateDumpFile in the host profile, configure the option to a fixed policy, and set value to false.

- **The Actions drop-down menu does not contain any items when your browser is set to language different from English**

When your browser is set to language different from English and you click the **Switch to New View** button from the virtual machine **Summary** tab of the vSphere Client inventory, the **Actions** drop-down menu in the **Guest OS** panel does not contain any items.

Workaround: Select the **Actions** drop-down menu on the top of the virtual machine page.

- **Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit minor throughput degradation when Dynamic Receive Side Scaling (DYN_RSS) or Generic RSS (GEN_RSS) feature is turned on**

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit less than 5 percent throughput degradation when DYN_RSS and GEN_RSS feature is turned on, which is unlikely to impact normal workloads.

Workaround: You can disable DYN_RSS and GEN_RSS feature with the following commands:

esxcli system module parameters set -m nmlx5_core -p "DYN_RSS=0 GEN_RSS=0"

reboot

- **RDMA traffic between two VMs on the same host might fail in PVRDMA environment**

In a vSphere 7.0 implementation of a PVRDMA environment, VMs pass traffic through the HCA for local communication if an HCA is present. However, loopback of RDMA traffic does not work on qedrntv driver. For instance, RDMA Queue Pairs running on VMs that are configured under same uplink port cannot communicate with each other.

In vSphere 6.7 and earlier, HCA was used for local RDMA traffic if SRQ was enabled. vSphere 7.0 uses HCA loopback with VMs using versions of PVRDMA that have SRQ enabled with a minimum of HW v14 using RoCE v2.

The current version of Marvell FastLinQ adapter firmware does not support loopback traffic between QPs of the same PF or port.

Workaround: Required support is being added in the out-of-box driver certified for vSphere 7.0. If you are using the inbox qedrntv driver, you must use a 3-host configuration and migrate VMs to the third host.

- **Unreliable Datagram traffic QP limitations in qedrntv driver**

There are limitations with the Marvell FastLinQ qedrntv RoCE driver and Unreliable Datagram (UD) traffic. UD applications involving bulk traffic might fail with qedrntv driver. Additionally, UD QPs can only work with DMA Memory Regions (MR). Physical MRs or FRMR are not supported. Applications attempting to use physical MR or FRMR along with UD QP fail to pass traffic when used with qedrntv driver. Known examples of such test applications are ibv_ud_pingpong and ib_send_bw.

Standard RoCE and RoCEv2 use cases in a VMware ESXi environment such as iSER, NVMe-oF (RoCE) and PVRDMA are not impacted by this issue. Use cases for UD traffic are limited and this issue impacts a small set of applications requiring bulk UD traffic.

Marvell FastLinQ hardware does not support RDMA UD traffic offload. In order to meet the VMware PVRDMA requirement to support GSI QP, a restricted software only implementation of UD QP support was added to the qedrntv driver. The goal of the implementation is to provide support for control path GSI communication and is not a complete implementation of UD QP supporting bulk traffic and advanced features.

Since UD support is implemented in software, the implementation might not keep up with heavy traffic and packets might be dropped. This can result in failures with bulk UD traffic.

Workaround: Bulk UD QP traffic is not supported with qedrntv driver and there is no workaround at this time. VMware ESXi RDMA (RoCE) use cases like iSER, NVMe, RDMA and PVRDMA are unaffected by this issue.

- **Servers equipped with QLogic 578xx NIC might fail when frequently connecting or disconnecting iSCSI LUNs**

If you trigger QLogic 578xx NIC iSCSI connection or disconnection frequently in a short time, the server might fail due to an issue with the qfle3 driver. This is caused by a known defect in the device's firmware.

Workaround: None.

- **ESXi might fail during driver unload or controller disconnect operation in Broadcom NVMe over FC environment**

In Broadcom NVMe over FC environment, ESXi might fail during driver unload or controller disconnect operation and display an error message such as: @BlueScreen: #PF Exception 14 in world 2098707:vmknvmeGener IP 0x4200225021cc addr 0x19

Workaround: None.

- **ESXi does not display OEM firmware version number of i350/X550 NICs on some Dell servers**

The inbox ixgben driver only recognizes firmware data version or signature for i350/X550 NICs. On some Dell servers the OEM firmware version number is programmed into the OEM package version region, and the inbox ixgben driver does not read this information. Only the 8-digit firmware signature is displayed.

Workaround: To display the OEM firmware version number, install async ixgben driver version 1.7.15 or later.

- **X710 or XL710 NICs might fail in ESXi**

When you initiate certain destructive operations to X710 or XL710 NICs, such as resetting the NIC or manipulating VMKernel's internal device tree, the NIC hardware might read data from non-packet memory.

Workaround: Do not reset the NIC or manipulate vmkernel internal device state.

- **NVMe-oF does not guarantee persistent VMHBA name after system reboot**

NVMe-oF is a new feature in vSphere 7.0. If your server has a USB storage installation that uses vmhba30+ and also has NVMe over RDMA configuration, the VMHBA name might change after a system reboot. This is because the VMHBA name assignment for NVMe over RDMA is different from PCIe devices. ESXi does not guarantee persistence.

Workaround: None.

- **Backup fails for vCenter database size of 300 GB or greater**

If the vCenter database size is 300 GB or greater, the file-based backup will fail with a timeout. The following error message is displayed: Timeout! Failed to complete in 72000 seconds

Workaround: None.

- **Checking the compliance state of a ESXi 7.0 host against a host profile with version 6.5 or 6.7, results in an error for vmhba and vmrdma devices**

When checking the compliance of a ESXi 7.0 host that uses nmlx5_core or nvme_pcie driver against a host profile with version 6.5 or 6.7, you may observe the following errors, where address1 and address2 are specific to the affected system.

- – A vmhba device with bus type logical, address1 is not present on your host.
  – A vmrdma device with bus type logical, address2 is not present on your host.

The error is due to a mismatch between device addresses generated by the nmlx5_core or nvme_pcie driver in ESXi version 7.0 and earlier.

Workaround: The error may be ignored. The ESXi host functionality is unaffected. To resolve the compliance state error, re-extract the host profile from a ESXi host version 7.0, and apply the new host profile to the host.

- **A restore of vCenter Server 7.0 which is upgraded from vCenter Server 6.x with External Platform Services Controller to vCenter Server 7.0 might fail**

When you restore a vCenter Server 7.0 which is upgraded from 6.x with External Platform Services Controller to vCenter Server 7.0, the restore might fail and display the following error: Failed to retrieve appliance storage list

Workaround: During the first stage of the restore process, increase the storage level of the vCenter Server 7.0. For example if the vCenter Server 6.7 External Platform Services Controller setup storage type is small, select storage type large for the restore process.

- **Enabled SSL protocols configuration parameter is not configured during a host profile remediation process**

Enabled SSL protocols configuration parameter is not configured during a host profile remediation and only the system default protocol tlsv1.2 is enabled. This behavior is observed for a host profile with version 7.0 and earlier in a vCenter Server 7.0 environment.

Workaround: To enable TLSV 1.0 or TLSV 1.1 SSL protocols for SFCB, log in to an ESXi host by using SSH, and run the following ESXCLI command: esxcli system wbem -P <protocol_name>

- **Unable to configure Lockdown Mode settings by using Host Profiles**

Lockdown Mode cannot be configured by using a security host profile and cannot be applied to multiple ESXi hosts at once. You must manually configure each host.

Workaround: In vCenter Server 7.0, you can configure Lockdown Mode and manage Lockdown Mode exception user list by using a security host profile.

- **When a host profile is applied to a cluster, Enhanced vMotion Compatibility (EVC) settings are missing from the ESXi hosts**

Some settings in the VMware config file /etc/vmware/config are not managed by Host Profiles and are blocked, when the config file is modified. As a result, when the host profile is applied to a cluster, the EVC settings are lost, which causes loss of EVC functionalities. For example, unmasked CPUs can be exposed to workloads.

Workaround: Reconfigure the relevant EVC baseline on cluster to recover the EVC settings.

- **Using a host profile that defines a core dump partition in vCenter Server 7.0 results in an error**

In vCenter Server 7.0, configuring and managing a core dump partition in a host profile is not available. Attempting to apply a host profile that defines a core dump partition, results in the following error: No valid coredump partition found.

Workaround: None. In vCenter Server 7.0., Host Profiles supports only file-based core dumps.

- **When a host profile is copied from an ESXi host or a host profile is edited, the user input values are lost**

Some of the host profile keys are generated from hash calculation even when explicit rules for key generation are provided. As a result, when you copy settings from a host or edit a host profile, the user input values in the answer file are lost.

Workaround: In vCenter Server 7.0, when a host profile is copied from an ESXi host or a host profile is modified, the user input settings are preserved.

- **HTTP requests from certain libraries to vSphere might be rejected**

The HTTP reverse proxy in vSphere 7.0 enforces stricter standard compliance than in previous releases. This might expose pre-existing problems in some third-party libraries used by applications for SOAP calls to vSphere.

If you develop vSphere applications that use such libraries or include applications that rely on such libraries in your vSphere stack, you might experience connection issues when these libraries send HTTP requests to VMOMI. For example, HTTP requests issued from vijava libraries can take the following form:

POST /sdk HTTP/1.1

SOAPAction

Content-Type: text/xml; charset=utf-8

User-Agent: Java/1.8.0_221

The syntax in this example violates an HTTP protocol header field requirement that mandates a colon after SOAPAction. Hence, the request is rejected in flight.

Workaround: Developers leveraging noncompliant libraries in their applications can consider using a library that follows HTTP standards instead. For example, developers who use the vijava library can consider using the latest version of the yavijava library instead.

- **Editing an advanced options parameter in a host profile and setting a value to false, results in setting the value to true**

When attempting to set a value to false for an advanced option parameter in a host profile, the user interface creates a non-empty string value. Values that are not empty are interpreted as true and the advanced option parameter receives a true value in the host profile.

Workaround: There are two possible workarounds.

- – Set the advanced option parameter to false on a reference ESXi host and copy settings from this host in Host Profiles.
  Note: The host must be compliant with the host profile before modifying the advanced option parameter on the host.
- – Set the advanced option parameter to false on a reference ESXi host and create a host profile from this host. Then copy the host profile settings from the new host profile to the existing host profile.

- **SNMP dynamic firewall ruleset is modified by Host Profiles during a remediation process**

The SNMP firewall ruleset is a dynamic state, which is handled during runtime. When a host profile is applied, the configuration of the ruleset is managed simultaneously by Host Profiles and SNMP, which can modify the firewall settings unexpectedly.

Workaround: There are two possible workarounds.

- – To allow the ruleset to manage itself dynamically, exclude the SNMP firewall ruleset option in the configuration of the host profile.
- – To proceed with the double management of the ruleset, when needed, correct the firewall ruleset state.

- **You might see a dump file when using Broadcom driver lsi_msgpt3, lsi_msgpt35 and lsi_mr3**

When using the lsi_msgpt3, lsi_msgpt35 and lsi_mr3 controllers, there is a potential risk to see dump file lsuv2-lsi-drivers-plugin-util-zdump. There is an issue when exiting the storelib used in this plugin utility. There is no impact on ESXi operations, you can ignore the dump file.

Workaround: You can safely ignore this message. You can remove the lsuv2-lsi-drivers-plugin with the following command: esxcli software vib remove -n lsuv2-lsiv2-drivers-plugin

- **You might see reboot is not required after configuring SR-IOV of a PCI device in vCenter, but device configurations made by third party extensions might be lost and require reboot to be re-applied.**

In ESXi 7.0, SR-IOV configuration is applied without a reboot and the device driver is reloaded. ESXi hosts might have third party extensions perform device configurations that need to run after the device driver is loaded during boot. A reboot is required for those third party extensions to re-apply the device configuration.

Workaround: You must reboot after configuring SR-IOV to apply third party device configurations.

VMware vCenter Server Photon OS Security Patches

This document contains the following sections

- Introduction
- Installation Steps
- vCenter Server Appliance Photon OS Security Patches

Introduction

This document tracks the release of 7.0.x patches to the Photon Operating System bundled in VMware vCenter Server.

You can download the deliverables from the Broadcom Support Portal. For download instructions, see Download Broadcom products and software.

Installation Steps

To apply the Photon OS security patches to the vCenter Server Appliance, you can use one of the methods.

- Deploy a new vCenter Server Appliance by using either the GUI or the CLI installer.
  For information about doing a fresh install of the vCenter Server Appliance, see Deploying the vCenter Server Appliance and Platform Services Controller Appliance.
- Upgrade to the version of the vCenter Server Appliance containing the latest Photon OS security patches by using either the GUI or the CLI installer.
  For information about upgrading the vCenter Server Appliance, see Upgrading the vCenter Server Appliance.
- Patch the appliance either by using the appliance shell or the Appliance Management Interface.
  For information on patching the vCenter Server Appliance, see Patching vCenter Server.
- Perform a file-based backup and restore where in the restore process you deploy a new appliance containing the latest Photon OS security patches..
  For information performing a file-based backup and restore of the vCenter Server Appliance, see Restore vCenter Server from a File-Based Backup.
- Migrate a vCenter Server on Windows instance to a version of the vCenter Server Appliance containing the latest Photon OS security patches.
  For information about performing a migration of vCenter Server on Windows to vCenter Server Appliance, see Migrating vCenter Server for Windows to vCenter Server Appliance.

vCenter Server Appliance Photon OS Security Patches

ESXi Update and Patch Release Notes

VMware ESXi 7.0 Update 3w Release Notes

This document contains the following sections

- Introduction
- What's New
- Patches Contained in This Release
- Upgrade Notes
- Patch Download and Installation
- Resolved Issues
- Known Issues from Previous Releases

Introduction

VMware ESXi 7.0 Update 3w | 15 JUL 2025 | Build 24784741
Check for additions and updates to these release notes.

IMPORTANT: If your source system contains hosts of versions between ESXi 7.0 Update 2 and Update 3c, and Intel drivers, before upgrading to ESXi 7.0 Update 3w, see the What's New section of the VMware vCenter Server 7.0 Update 3c Release Notes, because all content in the section is also applicable for vSphere 7.0 Update 3w. Also, see the related VMware knowledge base articles: 86447, 87258, and 87308.

What's New

- This release resolves CVE-2025-41236, CVE-2025-41237, CVE-2025-41238, and CVE-2025-41239. For more information on these vulnerabilities and their impact on Broadcom products, see VMSA-2025-0013.
- This release resolves CVE-2025-2884. Broadcom has evaluated the severity of this issue to be in the moderate severity range.

Patches Contained in This Release

This release of ESXi 7.0 Update 3w delivers the following patches:

Build Details

Download Filename:	VMware-ESXi-7.0U3w-24784741-depot.zip
Build:	24784741
Download Size:	419.5 MB
md5sum:	bc919e2febfb81b767e85e4fd33e75b8
sha256checksum:	11e8c973918df2f0a9720995f8481deaa8d6b56daf4e931971a0b903a871b944
Host Reboot Required:	Yes
Virtual Machine Migration or Shutdown Required:	Yes

Components

Component	Bulletin	Category	Severity
ESXi Component - core ESXi VIBs	ESXi_7.0.3-0.150.24784741	Security	Critical
ESXi Install/Upgrade Component	esx-update_7.0.3-0.150.24784741	Security	Critical

IMPORTANT:

- Starting with vSphere 7.0, VMware uses components for packaging VIBs along with bulletins. The `ESXi` and `esx-update` bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.
- When patching ESXi hosts by using VMware Update Manager from a version prior to ESXi 7.0 Update 2, it is strongly recommended to use the rollup bulletin in the patch baseline. If you cannot use the rollup bulletin, be sure to include *all* of the following packages in the patching baseline. If the following packages are not included in the baseline, the update operation fails:
  - VMware-vmkusb_0.1-1vmw.701.0.0.16850804 or higher
  - VMware-vmkata_0.1-1vmw.701.0.0.16850804 or higher
  - VMware-vmkfcoe_1.0.0.2-1vmw.701.0.0.16850804 or higher
  - VMware-NVMeoF-RDMA_1.0.1.2-1vmw.701.0.0.16850804 or higher

Rollup Bulletin

This rollup bulletin contains the latest VIBs with all the fixes after the initial release of ESXi 7.0.

Bulletin ID	Category	Severity	Details
ESXi70U3w-24784741	Security	Critical	Security only

Image Profiles

VMware patch and update releases contain general and critical image profiles. Application of the general release image profile applies to new bug fixes.

Image Profile Name
ESXi-7.0U3w-24784741-standard
ESXi-7.0U3w-24784741-no-tools

ESXi Image

Name and Version	Release Date	Category	Details
ESXi 7.0 U3w - 24784741	JULY 15 2025	Security	Security only

Upgrade Notes

The supported upgrade path from ESXi 7.0 Update 3w to ESXi 8.x is ESXi 8.0 Update 3g.

Patch Download and Installation

Log in to the Broadcom Support Portal to download this patch.

See these KBs for details on the authenticated online and offline download: 390121, 390098, and 389276.

In vSphere 7.x, the Update Manager plug-in, used for administering vSphere Update Manager, is replaced with the Lifecycle Manager plug-in. Administrative operations for vSphere Update Manager are still available under the Lifecycle Manager plug-in, along with new capabilities for vSphere Lifecycle Manager.

The typical way to apply patches to ESXi 7.x hosts is by using the vSphere Lifecycle Manager. For details, see About vSphere Lifecycle Manager and vSphere Lifecycle Manager Baselines and Images.

You can also update ESXi hosts without using the Lifecycle Manager plug-in, and use an image profile instead. To do this, you must manually download the patch offline bundle ZIP file.

For details, see Upgrading Hosts by Using ESXCLI Commands, and the VMware ESXi Upgrade guide.

Resolved Issues

The resolved issues are grouped as follows:

ESXi_7.0.3-0.150.24784741

Patch Category	Security
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs Included	• VMware_bootbank_native-misc-drivers_7.0.3-0.150.24784741

	• VMware_bootbank_vsan_7.0.3-0.150.24784741 • VMware_bootbank_bmcal_7.0.3-0.150.24784741 • VMware_bootbank_esx-xserver_7.0.3-0.150.24784741 • VMware_bootbank_gc_7.0.3-0.150.24784741 • VMware_bootbank_esx-base_7.0.3-0.150.24784741 • VMware_bootbank_esxio-combiner_7.0.3-0.150.24784741 • VMware_bootbank_trx_7.0.3-0.150.24784741 • VMware_bootbank_cpu-microcode_7.0.3-0.150.24784741 • VMware_bootbank_esx-dvfilter-generic-fastpath_7.0.3-0.150.24784741 • VMware_bootbank_vsanhealth_7.0.3-0.150.24784741 • VMware_bootbank_crx_7.0.3-0.150.24784741 • VMware_bootbank_vdfs_7.0.3-0.150.24784741
PRs Fixed	N/A
CVE numbers	CVE-2025-41236, CVE-2025-41237, CVE-2025-41238, CVE-2025-41239, CVE-2025-2884

The `ESXi` and `esx-update` bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.

This patch updates the `esx-base` VIB. Due to their dependency with the `esx-base` VIB, the following VIBs are updated with build number and patch version changes, but deliver no fixes: `native-misc-drivers`, `vsan`, `bmcal`, `esx-xserver`, `gc`, `esx-base`, `esxio-combiner`, `trx`, `cpu-microcode`, `esx-dvfilter-generic-fastpath`, `vsanhealth`, `crx`, and `vdfs` .

This patch resolves the following issues:

- This release resolves CVE-2025-41236, CVE-2025-41237, CVE-2025-41238, and CVE-2025-41239. For more information on these vulnerabilities and their impact on Broadcom products, see VMSA-2025-0013.
- This release resolves CVE-2025-2884. Broadcom has evaluated the severity of this issue to be in the moderate severity range.

esx-update_7.0.3-0.150.24784741

Patch Category	Security
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_bootbank_loadesx_7.0.3-0.150.24784741 • VMware_bootbank_esx-update_7.0.3-0.150.24784741
PRs Fixed	N/A
CVE numbers	N/A

Due to their dependency on the `esx-base` VIB, the following VIBs are updated with build number and patch version changes, but deliver no fixes: `loadesx` and `esx-update` .

ESXi-7.0U3w-24784741-standard

PRs Fixed	N/A
Related CVE numbers	CVE-2025-41236, CVE-2025-41237, CVE-2025-41238, CVE-2025-41239, CVE-2025-2884

This patch updates the following issues:

- This release resolves CVE-2025-41236, CVE-2025-41237, CVE-2025-41238, and CVE-2025-41239. For more information on these vulnerabilities and their impact on Broadcom products, see VMSA-2025-0013.
- This release resolves CVE-2025-2884. Broadcom has evaluated the severity of this issue to be in the moderate severity range.

ESXi-7.0U3w-24784741-no-tools

Profile Name	ESXi-7.0U3w-24784741-no-tools
Build	For build information, see the Patches Contained in This Release section.
Vendor	Broadcom, Inc.
Release Date	July 15, 2025
Acceptance Level	PartnerSupported
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_bootbank_native-misc-drivers_7.0.3-0.150.24784741

This patch updates the following issues:

- This release resolves CVE-2025-41236, CVE-2025-41237, CVE-2025-41238, and CVE-2025-41239. For more information on these vulnerabilities and their impact on Broadcom products, see VMSA-2025-0013.
- This release resolves CVE-2025-2884. Broadcom has evaluated the severity of this issue to be in the moderate severity range.

ESXi 7.0 U3w - 24784741

Name	ESXi
Version	ESXi 7.0 U3w - 24784741
Release Date	July 15, 2025
Category	Security
Affected Components	• ESXi Component - core ESXi • ESXi Install/Upgrade
PRs Fixed	N/A
Related CVE numbers	CVE-2025-41236, CVE-2025-41237, CVE-2025-41238, CVE-2025-41239, CVE-2025-2884

This patch resolves the issues listed in the ESXi-7.0U3w-24784741-standard image profile.

Known Issues from Previous Releases

vSphere Cluster Services Issues

You see compatibility issues in new vCLS VMs deployed in vSphere 7.0 Update 3 environment

The default name for new vCLS VMs deployed in vSphere 7.0 Update 3 environment uses the pattern vCLS-UUID. vCLS VMs created in earlier vCenter Server versions continue to use the pattern vCLS (n). Since the use of parenthesis () is not supported by many solutions that interoperate with vSphere, you might see compatibility issues.

Workaround: Reconfigure vCLS by using retreat mode after updating to vSphere 7.0 Update 3.

Installation, Upgrade, and Migration Issues

The vCenter Upgrade/Migration pre-checks fail with "Unexpected error 87"

The vCenter Server Upgrade/Migration pre-checks fail when the Security Token Service (STS) certificate does not contain a Subject Alternative Name (SAN) field. This situation occurs when you have replaced the vCenter 5.5 Single Sign-On certificate with a custom certificate that has no SAN field, and you attempt to upgrade to vCenter Server 7.0. The upgrade considers the STS certificate invalid and the pre-checks prevent the upgrade process from continuing.

Workaround: Replace the STS certificate with a valid certificate that contains a SAN field then proceed with the vCenter Server 7.0 Upgrade/Migration.

Corrupted VFAT partitions from a vSphere 6.7 environment might cause upgrades to ESXi 7.x to fail

Due to corrupted VFAT partitions from a vSphere 6.7 environment, repartitioning the boot disks of an ESXi host might fail during an upgrade to ESXi 7.x. As a result, you might see the following errors:

When upgrading to ESXi 7.0 Update 3l, the operation fails with a purple diagnostic screen and/or an error such as:

- `An error occurred while backing up VFAT partition files before re-partitioning: Failed to calculate size for temporary Ramdisk: <error>.`
- `An error occurred while backing up VFAT partition files before re-partitioning: Failed to copy files to Ramdisk: <error>.`
  If you use an ISO installer, you see the errors, but no purple diagnostic screen.

When upgrading to an ESXi 7.x version earlier than 7.0 Update 3l, you might see:

- Logs such as `ramdisk (root) is full` in the `vmkwarning.log` file.
- Unexpected rollback to ESXi 6.5 or 6.7 on reboot.
- The `/bootbank` ,`/altbootbank` , and ESX-OSData partitions are not present.

Workaround: You must first remediate the corrupted partitions before completing the upgrade to ESXi 7.x. For more details, see VMware knowledge base article 91136.

Problems upgrading to vSphere 7.0 with pre-existing CIM providers

After upgrade, previously installed 32-bit CIM providers stop working because ESXi requires 64-bit CIM providers. Customers may lose management API functions related to CIMPDK, NDDK (native DDK), HEXDK, VAIODK (IO filters), and see errors related to **uwglibc** dependency.

The syslog reports module missing, "32 bit shared libraries not loaded."

Workaround: There is no workaround. The fix is to download new 64-bit CIM providers from your vendor.

Installation of 7.0 Update 1 drivers on ESXi 7.0 hosts might fail

You cannot install drivers applicable to ESXi 7.0 Update 1 on hosts that run ESXi 7.0 or 7.0b.

The operation fails with an error, such as:

```
VMW_bootbank_qedrntv_3.40.4.0-12vmw.701.0.0.xxxxxxx requires vmkapi_2_7_0_0, but the requirement cannot be satisfied within the ImageProfile. Please refer to the log file for more details.
```

Workaround: Update the ESXi host to 7.0 Update 1. Retry the driver installation.

UEFI booting of ESXi hosts might stop with an error during an update to ESXi 7.0 Update 2 from an earlier version of ESXi 7.0

If you attempt to update your environment to 7.0 Update 2 from an earlier version of ESXi 7.0by using vSphere Lifecycle Manager patch baselines, UEFI booting of ESXi hosts might stop with an error such as:

```
Loading /boot.cfgFailed to load crypto64.efiFatal error: 15 (Not found)
```

Workaround: For more information, see VMware knowledge base articles 83063 and 83107 .

If legacy VIBs are in use on an ESXi host, vSphere Lifecycle Manager cannot extract a desired software specification to seed to a new cluster

With vCenter Server 7.0 Update 2, you can create a new cluster by importing the desired software specification from a single reference host. However, if legacy VIBs are in use on an ESXi host, vSphere Lifecycle Manager cannot extract in the vCenter Server instance where you create the cluster a reference software specification from such a host. In the `/var/log/lifecycle.log` , you see messages such as:

```
020-11-11T06:54:03Z lifecycle: 1000082644: HostSeeding:499
ERROR Extract depot failed: Checksum doesn't match. Calculated
5b404e28e83b1387841bb417da93c8c796ef2497c8af0f79583fd54e789d8826, expected:
0947542e30b794c721e21fb595f1851b247711d0619c55489a6a8cae6675e796 2020-11-11T06:54:04Z
lifecycle: 1000082644: imagemanagerctl:366 ERROR Extract depot failed.
2020-11-11T06:54:04Z lifecycle: 1000082644: imagemanagerctl:145 ERROR [VibChecksumError]
```

Workaround: Follow the steps described in VMware knowledge base article 83042.

You see a short burst of log messages in the syslog.log after every ESXi boot

After updating to ESXi 7.0 Update 2, you might see a short burst of log messages after every ESXi boot.

Such logs do not indicate any issue with ESXi and you can ignore these messages. For example:

```
2021-01-19T22:44:22Z watchdog-vaai-nasd: '/usr/lib/vmware/nfs/bin/vaai-nasd -f'
exited after 0 seconds (quick failure 127) 12021-01-19T22:44:22Z watchdog-vaai-
nasd: Executing '/usr/lib/vmware/nfs/bin/vaai-nasd -f'2021-01-19T22:44:22.990Z
aainasd[1000051135]: Log for VAAI-NAS Daemon for NFS version=1.0 build=build-00000
option=DEBUG2021-01-19T22:44:22.990Z vaainasd[1000051135]: DictionaryLoadFile: No entries

vaainasd[1000051135]: DISKLIB-PLUGIN : Not loading plugin /usr/lib/vmware/nas_plugins/
lib64: Not a shared library.
```

Workaround: None

You see warning messages for missing VIBs in vSphere Quick Boot compatibility check reports

After you upgrade to ESXi 7.0 Update 2, if you check vSphere Quick Boot compatibility of your environment by using the `/usr/lib/vmware/loadesx/bin/loadESXCheckCompat.py` command, you might see some warning messages for missing VIBs in the shell. For example:

```
Cannot find VIB(s) ... in the given VIB collection.Ignoring missing reserved VIB(s) ...,
they are removed from reserved VIB IDs.
```

Such warnings do not indicate a compatibility issue.

Workaround: The missing VIB messages can be safely ignored and do not affect the reporting of vSphere Quick Boot compatibility. The final output line of the `loadESXCheckCompat` command unambiguously indicates if the host is compatible.

Auto bootstrapping a cluster that you manage with a vSphere Lifecycle Manager image fails with an error

If you attempt auto bootstrapping a cluster that you manage with a vSphere Lifecycle Manager image to perform a stateful install and overwrite the VMFS partitions, the operation fails with an error. In the support bundle, you see messages such as:

```
2021-02-11T19:37:43Z Host Profiles[265671 opID=MainThread]: ERROR:
EngineModule::ApplyHostConfig. Exception: [Errno 30] Read-only file system
```

Workaround: Follow vendor guidance to clean the VMFS partition in the target host and retry the operation. Alternatively, use an empty disk. For more information on the disk-partitioning utility on ESXi, see VMware knowledge base article 1036609.

Upgrades to ESXi 7.x from 6.5.x and 6.7.0 by using ESXCLI might fail due to a space limitation

Upgrades to ESXi 7.x from 6.5.x and 6.7.0 by using the `esxcli software profile update` or `esxcli software profile install` ESXCLI commands might fail, because the ESXi bootbank might be less than the size of the image profile. In the ESXi Shell or the PowerCLI shell, you see an error such as:

```
[InstallationError]
 The pending transaction requires 244 MB free space, however the maximum supported size is 239 MB.
 Please refer to the log file for more details.
```

The issue also occurs when you attempt an ESXi host upgrade by using the ESXCLI commands `esxcli software vib update` or `esxcli software vib install`.

Workaround: You can perform the upgrade in two steps, by using the `esxcli software profile update` command to update ESXi hosts to ESXi 6.7 Update 1 or later, and then update to 7.0 Update 1c. Alternatively, you can run an upgrade by using an ISO image and the vSphere Lifecycle Manager.

You cannot migrate linked clones across vCenter Servers

If you migrate a linked clone across vCenter Servers, operations such as power on and delete might fail for the source virtual machine with an `Invalid virtual machine state` error.

Workaround: Keep linked clones on the same vCenter Server as the source VM. Alternatively, promote the linked clone to full clone before migration.

Migration across vCenter Servers of virtual machines with many virtual disks and snapshot levels to a datastore on NVMe over TCP storage might fail

Migration across vCenter Servers of virtual machines with more than 180 virtual disks and 32 snapshot levels to a datastore on NVMe over TCP storage might fail. The ESXi host preemptively fails with an error such as `The migration has exceeded the maximum switchover time of 100 second(s)`.

Workaround: None

A virtual machine with enabled Virtual Performance Monitoring Counters (VPMC) might fail to migrate between ESXi hosts

If you try to migrate a virtual machine with enabled VPMC by using vSphere vMotion, the operation might fail if the target host is using some of the counters to compute memory or performance statistics. The operation fails with an error such as `A performance counter used by the guest is not available on the host CPU`.

Workaround: Power off the virtual machine and use cold migration. For more information, see VMware knowledge base article 81191.

If a live VIB install, upgrade, or remove operation immediately precedes an interactive or scripted upgrade to ESXi 7.0 Update 3 by using the installer ISO, the upgrade fails

When a VIB install, upgrade, or remove operation immediately precedes an interactive or scripted upgrade to ESXi 7.0 Update 3 by using the installer ISO, the ConfigStore might not keep some configurations of the upgrade. As a result, ESXi hosts become inaccessible after the upgrade operation, although the upgrade seems successful. To prevent this issue, the ESXi 7.0 Update 3 installer adds a temporary check to block such scenarios. In the ESXi installer console, you see the following error message: `Live VIB installation, upgrade or removal may cause subsequent ESXi upgrade to fail when using the ISO installer.`

Workaround: Use an alternative upgrade method to avoid the issue, such as using ESXCLI or the vSphere Lifecycle Manager.

Smart Card and RSA SecurID authentication might stop working after upgrading to vCenter Server 7.0

If you have configured vCenter Server for either Smart Card or RSA SecurID authentication, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057 before starting the vSphere 7.0 upgrade process. If you do not perform the workaround as described in the KB, you might see the following error messages and Smart Card or RSA SecurID authentication does not work.

"Smart card authentication may stop working. Smart card settings may not be preserved, and smart card authentication may stop working."

or

"RSA SecurID authentication may stop working. RSA SecurID settings may not be preserved, and RSA SecurID authentication may stop working."

Workaround: Before upgrading to vSphere 7.0, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057.

The vlanid property in custom installation scripts might not work

If you use a custom installation script that sets the `vlanid` property to specify a desired VLAN, the property might not take effect on newly installed ESXi hosts. The issue occurs only when a physical NIC is already connected to DHCP when the installation starts. The `vlanid` property works properly when you use a newly connected NIC.

Workaround: Manually set the VLAN from the Direct Console User Interface after you boot the ESXi host. Alternatively, disable the physical NIC and then boot the host.

HPE servers with Trusted Platform Module (TPM) boot, but remote attestation fails

Some HPE servers do not have enough event log space to properly finish TPM remote attestation. As a result, the VMkernel boots, but remote attestation fails due to the truncated log.

Workaround: None.

Upgrading a vCenter Server with an external Platform Services Controller from 6.7u3 to 7.0 fails with VMAFD error

When you upgrade a vCenter Server deployment using an external Platform Services Controller, you converge the Platform Services Controller into a vCenter Server appliance. If the upgrade fails with the error `install.vmafd.vmdir_vdcpromo_error_21`, the VMAFD firstboot process has failed. The VMAFD firstboot process copies the VMware Directory Service Database (data.mdb) from the source Platform Services Controller and replication partner vCenter Server appliance.

Workaround: Disable TCP Segmentation Offload (TSO) and Generic Segmentation Offload (GSO) on the Ethernet adapter of the source Platform Services Controller or replication partner vCenter Server appliance before upgrading a vCenter Server with an external Platform Services Controller. See Knowledge Base article: https://kb.vmware.com/s/article/74678

Smart card and RSA SecurID settings may not be preserved during vCenter Server upgrade

Authentication using RSA SecurID will not work after upgrading to vCenter Server 7.0. An error message will alert you to this issue when attempting to login using your RSA SecurID login.

Workaround: Reconfigure the smart card or RSA SecureID.

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with network error message

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with the error message `IP already exists in the network`. This prevents the migration process from configuring the network parameters on the new vCenter Server appliance. For more information, examine the log file: `/var/log/vmware/upgrade/UpgradeRunner.log`

Workaround:

1. Verify that all Windows Updates have been completed on the source vCenter Server for Windows instance, or disable automatic Windows Updates until after the migration finishes.
2. Retry the migration of vCenter Server for Windows to vCenter Server appliance 7.0.

When you configure the number of virtual functions for an SR-IOV device by using the max_vfs module parameter, the changes might not take effect

In vSphere 7.0, you can configure the number of virtual functions for an SR-IOV device by using the Virtual Infrastructure Management (VIM) API, for example, through the vSphere Client. The task does not require reboot of the ESXi host. After you use the VIM API configuration, if you try to configure the number of SR-IOV virtual functions by using the `max_vfs` module parameter, the changes might not take effect because they are overridden by the VIM API configuration.

Workaround: None. To configure the number of virtual functions for an SR-IOV device, use the same method every time. Use the VIM API or use the `max_vfs` module parameter and reboot the ESXi host.

Upgraded vCenter Server appliance instance does not retain all the secondary networks (NICs) from the source instance

During a major upgrade, if the source instance of the vCenter Server appliance is configured with multiple secondary networks other than the VCHA NIC, the target vCenter Server instance will not retain secondary networks other than the VCHA NIC. If the source instance is configured with multiple NICs that are part of VDS port groups, the NIC configuration will not be preserved during the upgrade. Configurations for vCenter Server appliance instances that are part of the standard port group will be preserved.

Workaround: None. Manually configure the secondary network in the target vCenter Server appliance instance.

After upgrading or migrating a vCenter Server with an external Platform Services Controller, users authenticating using Active Directory lose access to the newly upgraded vCenter Server instance

After upgrading or migrating a vCenter Server with an external Platform Services Controller, if the newly upgraded vCenter Server is not joined to an Active Directory domain, users authenticating using Active Directory will lose access to the vCenter Server instance.

Workaround: Verify that the new vCenter Server instance has been joined to an Active Directory domain. See Knowledge Base article: https://kb.vmware.com/s/article/2118543

Migrating a vCenter Server for Windows with an external Platform Services Controller using an Oracle database fails

If there are non-ASCII strings in the Oracle events and tasks table the migration can fail when exporting events and tasks data. The following error message is provided: UnicodeDecodeError

Workaround: None.

After an ESXi host upgrade, a Host Profile compliance check shows non-compliant status while host remediation tasks fail

The non-compliant status indicates an inconsistency between the profile and the host.

This inconsistency might occur because ESXi 7.0 does not allow duplicate claim rules, but the profile you use contains duplicate rules. For example, if you attempt to use the Host Profile that you extracted from the host before upgrading ESXi 6.5 or ESXi 6.7 to version 7.0 and the Host Profile contains any duplicate claim rules of system default rules, you might experience the problems.

Workaround:

1. Remove any duplicate claim rules of the system default rules from the Host Profile document.
2. Check the compliance status.
3. Remediate the host.
4. If the previous steps do not help, reboot the host.

Error message displays in the vCenter Server Management Interface

After installing or upgrading to vCenter Server 7.0, when you navigate to the Update panel within the vCenter Server Management Interface, the error message "Check the URL and try again" displays. The error message does not prevent you from using the functions within the Update panel, and you can view, stage, and install any available updates.

Workaround: None.

Security Features Issues

Turn off the Service Location Protocol service in ESXi, slpd, to prevent potential security vulnerabilities

Some services in ESXi that run on top of the host operating system, including slpd, the CIM object broker, sfcbd, and the related openwsmand service, have proven security vulnerabilities. VMware has addressed all known vulnerabilities in VMSA-2019-0022 and VMSA-2020-0023, and the fixes are part of the vSphere 7.0 Update 2 release. While sfcbd and openwsmand are disabled by default in ESXi, slpd is enabled by default and you must turn it off, if not necessary, to prevent exposure to a future vulnerability after an upgrade.

Workaround: To turn off the slpd service, run the following PowerCLI commands:

```
$ Get-VMHost | Get-VmHostService | Where-Object {$_.key -eq “slpd”} | Set-VMHostService -policy “off”$ Get-VMHost | Get-VmHostService | Where-Object {$_.key -eq “slpd”} | Stop-VMHostService -Confirm:$false
```

Alternatively, you can use the command `chkconfig slpd off && /etc/init.d/slpd stop`.

The openwsmand service is not on the ESXi services list and you can check the service state by using the following PowerCLI commands:

```
$esx=(Get-EsxCli -vmhost xx.xx.xx.xx -v2)$esx.system.process.list.invoke() | where CommandLine -like '*openwsman*' | select commandline
```

In the ESXi services list, the sfcbd service appears as sfcbd-watchdog.

For more information, see VMware knowledge base articles 76372 and 1025757.

Encrypted virtual machine fails to power on when HA-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled HA on the Trusted Cluster and one or more hosts in the cluster fails attestation, an encrypted virtual machine cannot power on.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Encrypted virtual machine fails to power on when DRS-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled DRS on the Trusted Cluster and one or more hosts in the cluster fails attestation, DRS might try to power on an encrypted virtual machine on an unattested host in the cluster. This operation puts the virtual machine in a locked state.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Migrating or cloning encrypted virtual machines across vCenter Server instances fails when attempting to do so using the vSphere Client

If you try to migrate or clone an encrypted virtual machine across vCenter Server instances using the vSphere Client, the operation fails with the following error message: "The operation is not allowed in the current state."

Workaround: You must use the vSphere APIs to migrate or clone encrypted virtual machines across vCenter Server instances.

Networking Issues

Reduced throughput in networking performance on Intel 82599/X540/X550 NICs

The new queue-pair feature added to ixgben driver to improve networking performance on Intel 82599EB/X540/X550 series NICs might reduce throughput under some workloads in vSphere 7.0 as compared to vSphere 6.7.

Workaround: To achieve the same networking performance as vSphere 6.7, you can disable the queue-pair with a module parameter. To disable the queue-pair, run the command:

```
# esxcli system module parameters set -p "QPair=0,0,0,0..." -m ixgben
```

After running the command, reboot.

One or more I/O devices do not generate interrupts when the AMD IOMMU is in use

If the I/O devices on your ESXi host provide more than a total of 512 distinct interrupt sources, some sources are erroneously assigned an interrupt-remapping table entry (IRTE) index in the AMD IOMMU that is greater than the maximum value. Interrupts from such a source are lost, so the corresponding I/O device behaves as if interrupts are disabled.

Workaround: Use the ESXCLI command `esxcli system settings kernel set -s iovDisableIR -v true` to disable the AMD IOMMU interrupt remapper. Reboot the ESXi host so that the command takes effect.

When you set auto-negotiation on a network adapter, the device might fail

In some environments, if you set link speed to auto-negotiation for network adapters by using the command `esxcli network nic set -a -n vmmicx` , the devices might fail and reboot does not recover connectivity. The issue is specific to a combination of some Intel X710/X722 network adapters, a SFP+ module and a physical switch, where auto-negotiate speed/duplex scenario is not supported.

Workaround: Make sure you use an Intel-branded SFP+ module. Alternatively, use a Direct Attach Copper (DAC) cable.

Solarflare x2542 and x2541 network adapters configured in 1x100G port mode achieve throughput of up to 70Gbps in a vSphere environment

vSphere 7.0 Update 2 supports Solarflare x2542 and x2541 network adapters configured in 1x100G port mode. However, you might see a hardware limitation in the devices that causes the actual throughput to be up to some 70Gbps in a vSphere environment.

Workaround: None

VLAN traffic might fail after a NIC reset

A NIC with PCI device ID 8086:1537 might stop to send and receive VLAN tagged packets after a reset, for example, with a command `vsish -e set /net/pNics/vmnic0/reset 1`.

Workaround: Avoid resetting the NIC. If you already face the issue, use the following commands to restore the VLAN capability, for example at vmnic0:

```
# esxcli network nic software set --tagging=1 -n vmnic0# esxcli network nic software set --tagging=0 -n vmnic0
```

Any change in the NetQueue balancer settings causes NetQueue to be disabled after an ESXi host reboot

Any change in the NetQueue balancer settings by using the command `esxcli/localcli network nic queue loadbalancer set -n <nicname> --<lb_setting>` causes NetQueue, which is enabled by default, to be disabled after an ESXi host reboot.

Workaround: After a change in the NetQueue balancer settings and host reboot, use the command `configstorecli config current get -c esx -g network -k nics` to retrieve ConfigStore data to verify whether the `/esx/network/nics/net_queue/load_balancer/enable` is working as expected.

After you run the command, you see output similar to:

```
{"mac": "02:00:0e:6d:14:3e","name": "vmnic1","net_queue": { "load_balancer": { "dynamic_pool": true, "enable": true }},"virtual_mac": "00:50:56:5a:21:11"}
```

If the output is not as expected, for example `"load_balancer": "enable": false"`, run the following command:

```
esxcli/localcli network nic queue loadbalancer state set -n <nicname> -e true
```

Paravirtual RDMA (PVRDMA) network adapters do not support NSX networking policies

If you configure an NSX distributed virtual port for use in PVRDMA traffic, the RDMA protocol traffic over the PVRDMA network adapters does not comply with the NSX network policies.

Workaround: Do not configure NSX distributed virtual ports for use in PVRDMA traffic.

Rollback from converged vSphere Distributed Switch (VDS) to NSX-T VDS is not supported in vSphere 7.0 Update 3

Rollback from converged VDS that supports both vSphere 7 traffic and NSX-T 3 traffic on the same VDS to one N-VDS for NSX-T traffic is not supported in vSphere 7.0 Update 3.

Workaround: None

If you do not set the nmlx5 network driver module parameter, network connectivity or ESXi hosts might fail

If you do not set the `supported_num_ports` module parameter for the `nmlx5_core` driver on an ESXi host with multiple network adapters of versions Mellanox ConnectX-4, Mellanox ConnectX-5 and Mellanox ConnectX-6, the driver might not allocate sufficient memory for operating all the NIC ports for the host. As a result, you might experience network loss or ESXi host failure with purple diagnostic screen, or both.

Workaround: Set the `supported_num_ports` module parameter value in the `nmlx5_core` network driver equal to the total number of Mellanox ConnectX-4, Mellanox ConnectX-5 and Mellanox ConnectX-6 network adapter ports on the ESXi host.

High throughput virtual machines may experience degradation in network performance when Network I/O Control (NetIOC) is enabled

Virtual machines requiring high network throughput can experience throughput degradation when upgrading from vSphere 6.7 to vSphere 7.0 with NetIOC enabled.

Workaround: Adjust the `ethernetx.ctxPerDev` setting to enable multiple worlds.

IPv6 traffic fails to pass through VMkernel ports using IPsec

When you migrate VMkernel ports from one port group to another, IPv6 traffic does not pass through VMkernel ports using IPsec.

Workaround: Remove the IPsec security association (SA) from the affected server, and then reapply the SA. To learn how to set and remove an IPsec SA, see the *vSphere Security* documentation.

Higher ESX network performance with a portion of CPU usage increase

ESX network performance may increase with a portion of CPU usage.

Workaround: Remove and add the network interface with only 1 rx dispatch queue. For example:

```
esxcli network ip interface remove --interface-name=vmk1
```

```
esxcli network ip interface add --interface-name=vmk1 --num-rxqueue=1
```

VM might lose Ethernet traffic after hot-add, hot-remove or storage vMotion

A VM might stop receiving Ethernet traffic after a hot-add, hot-remove or storage vMotion. This issue affects VMs where the uplink of the VNIC has SR-IOV enabled. PVRDMA virtual NIC exhibits this issue when the uplink of the virtual network is a Mellanox RDMA capable NIC and RDMA namespaces are configured.

Workaround: You can hot-remove and hot-add the affected Ethernet NICs of the VM to restore traffic. On Linux guest operating systems, restarting the network might also resolve the issue. If these workarounds have no effect, you can reboot the VM to restore network connectivity.

Change of IP address for a VCSA deployed with static IP address requires that you create the DNS records in advance

With the introduction of the DDNS, the DNS record update only works for VCSA deployed with DHCP configured networking. While changing the IP address of the vCenter server via VAMI, the following error is displayed:

The specified IP address does not resolve to the specified hostname.

Workaround: There are two possible workarounds.

1. Create an additional DNS entry with the same FQDN and desired IP address. Log in to the VAMI and follow the steps to change the IP address.
2. Log in to the VCSA using ssh. Execute the following script:
   `./opt/vmware/share/vami/vami_config_net`
   Use option 6 to change the IP adddress of eth0. Once changed, execute the following script:
   `./opt/likewise/bin/lw-update-dns`
   Restart all the services on the VCSA to update the IP information on the DNS server.

It may take several seconds for the NSX Distributed Virtual Port Group (NSX DVPG) to be removed after deleting the corresponding logical switch in NSX Manager.

As the number of logical switches increases, it may take more time for the NSX DVPG in vCenter Server to be removed after deleting the corresponding logical switch in NSX Manager. In an environment with 12000 logical switches, it takes approximately 10 seconds for an NSX DVPG to be deleted from vCenter Server.

Workaround: None.

Hostd runs out of memory and fails if a large number of NSX Distributed Virtual port groups are created.

In vSphere 7.0, NSX Distributed Virtual port groups consume significantly larger amounts of memory than opaque networks. For this reason, NSX Distributed Virtual port groups can not support the same scale as an opaque network given the same amount of memory.

Workaround:To support the use of NSX Distributed Virtual port groups, increase the amount of memory in your ESXi hosts. If you verify that your system has adequate memory to support your VMs, you can directly increase the memory of `hostd` using the following command.

```
localcli --plugin-dir /usr/lib/vmware/esxcli/int/ sched group setmemconfig --group-path
host/vim/vmvisor/hostd --units mb --min 2048 --max 2048
```

Note that this will cause `hostd` to use memory normally reserved for your environment's VMs. This may have the affect of reducing the number of VMs your ESXi host can support.

DRS may incorrectly launch vMotion if the network reservation is configured on a VM

If the network reservation is configured on a VM, it is expected that DRS only migrates the VM to a host that meets the specified requirements. In a cluster with NSX transport nodes, if some of the transport nodes join the transport zone by NSX-T Virtual Distributed Switch (N-VDS), and others by vSphere Distributed Switch (VDS) 7.0, DRS may incorrectly launch vMotion. You might encounter this issue when:

- The VM connects to an NSX logical switch configured with a network reservation.
- Some transport nodes join transport zone using N-VDS, and others by VDS 7.0, or, transport nodes join the transport zone through different VDS 7.0 instances.

Workaround: Make all transport nodes join the transport zone by N-VDS or the same VDS 7.0 instance.

When adding a VMkernel NIC (vmknic) to an NSX portgroup, vCenter Server reports the error "Connecting VMKernel adapter to a NSX Portgroup on a Stateless host is not a supported operation. Please use Distributed Port Group instead."

- For stateless ESXi on Distributed Virtual Switch (VDS), the vmknic on a NSX port group is blocked. You must instead use a Distributed Port Group.
- For stateful ESXi on VDS, vmknic on NSX port group is supported, but vSAN may have an issue if it is using vmknic on a NSX port group.

Workaround: Use a Distributed Port Group on the same VDS.

Enabling SRIOV from vCenter for QLogic 4x10GE QL41164HFCU CNA might fail

If you navigate to the **Edit Settings** dialog for physical network adapters and attempt to enable SR-IOV, the operation might fail when using QLogic 4x10GE QL41164HFCU CNA. Attempting to enable SR-IOV might lead to a network outage of the ESXi host.

Workaround: Use the following command on the ESXi host to enable SRIOV:

```
esxcfg-module
```

vCenter Server fails if the hosts in a cluster using Distributed Resource Scheduler (DRS) join NSX-T networking by a different Virtual Distributed Switch (VDS) or combination of NSX-T Virtual Distributed Switch (NVDS) and VDS

In vSphere 7.0, when using NSX-T networking on vSphere VDS with a DRS cluster, if the hosts do not join the NSX transport zone by the same VDS or NVDS, it can cause vCenter Server to fail.

Workaround: Have hosts in a DRS cluster join the NSX transport zone using the same VDS or NVDS.

Storage Issues

VMFS datastores are not mounted automatically after disk hot remove and hot insert on HPE Gen10 servers with SmartPQI controllers

When SATA disks on HPE Gen10 servers with SmartPQI controllers without expanders are hot removed and hot inserted back to a different disk bay of the same machine, or when multiple disks are hot removed and hot inserted back in a different order, sometimes a new local name is assigned to the disk. The VMFS datastore on that disk appears as a snapshot and will not be mounted back automatically because the device name has changed.

Workaround: None. SmartPQI controller does not support unordered hot remove and hot insert operations.

VOMA check on NVMe based VMFS datastores fails with error

VOMA check is not supported for NVMe based VMFS datastores and will fail with the error:

```
ERROR: Failed to reserve device. Function not implemented
```

Example:

```
# voma -m vmfs -f check -d /vmfs/devices/disks/: <partition#>
Running VMFS Checker version 2.1 in check mode
Initializing LVM metadata, Basic Checks will be done

Checking for filesystem activity
Performing filesystem liveness check..|Scanning for VMFS-6 host activity (4096 bytes/HB, 1024 HBs).
ERROR: Failed to reserve device. Function not implemented
Aborting VMFS volume check
VOMA failed to check device : General Error
```

Workaround: None. If you need to analyse VMFS metadata, collect it using the `-l` option, and pass to VMware customer support. The command for collecting the dump is:

```
voma -l -f dump -d /vmfs/devices/disks/:<partition#>
```

Using the VM reconfigure API to attach an encrypted First Class Disk to an encrypted virtual machine might fail with error

If an FCD and a VM are encrypted with different crypto keys, your attempts to attach the encrypted FCD to the encrypted VM using the `VM reconfigure API` might fail with the error message:

```
Cannot decrypt disk because key or password is incorrect.
```

Workaround: Use the `attachDisk API` rather than the `VM reconfigure API` to attach an encrypted FCD to an encrypted VM.

ESXi host might get in non responding state if a non-head extent of its spanned VMFS datastore enters the Permanent Device Loss (PDL) state

This problem does not occur when a non-head extent of the spanned VMFS datastore fails along with the head extent. In this case, the entire datastore becomes inaccessible and no longer allows I/Os.

In contrast, when only a non-head extent fails, but the head extent remains accessible, the datastore heartbeat appears to be normal. And the I/Os between the host and the datastore continue. However, any I/Os that depend on the failed non-head extent start failing as well. Other I/O transactions might accumulate while waiting for the failing I/Os to resolve, and cause the host to enter the non responding state.

Workaround: Fix the PDL condition of the non-head extent to resolve this issue.

Virtual NVMe Controller is the default disk controller for Windows 10 guest operating systems

The Virtual NVMe Controller is the default disk controller for the following guest operating systems when using Hardware Version 15 or later:

Windows 10

Windows Server 2016

Windows Server 2019

Some features might not be available when using a Virtual NVMe Controller. For more information, see https://kb.vmware.com/s/article/2147714

Note: Some clients use the previous default of LSI Logic SAS. This includes ESXi host client and PowerCLI.

Workaround: If you need features not available on Virtual NVMe, switch to VMware Paravirtual SCSI (PVSCSI) or LSI Logic SAS. For information on using VMware Paravirtual SCSI (PVSCSI), see https://kb.vmware.com/s/article/1010398

After an ESXi host upgrade to vSphere 7.0, presence of duplicate core claim rules might cause unexpected behavior

Claim rules determine which multipathing plugin, such as NMP, HPP, and so on, owns paths to a particular storage device. ESXi 7.0 does not support duplicate claim rules. However, the ESXi 7.0 host does not alert you if you add duplicate rules to the existing claim rules inherited through an upgrade from a legacy release. As a result of using duplicate rules, storage devices might be claimed by unintended plugins, which can cause unexpected outcome.

Workaround: Do not use duplicate core claim rules. Before adding a new claim rule, delete any existing matching claim rule.

A CNS query with the compliance status filter set might take unusually long time to complete

The CNS QueryVolume API enables you to obtain information about the CNS volumes, such as volume health and compliance status. When you check the compliance status of individual volumes, the results are obtained quickly. However, when you invoke the CNS QueryVolume API to check the compliance status of multiple volumes, several tens or hundreds, the query might perform slowly.

Workaround: Avoid using bulk queries. When you need to get compliance status, query one volume at a time or limit the number of volumes in the query API to 20 or fewer. While using the query, avoid running other CNS operations to get the best performance.

A VMFS datastore backed by an NVMe over Fabrics namespace or device might become permanently inaccessible after recovering from an APD or PDL failure

If a VMFS datastore on an ESXi host is backed by an NVMe over Fabrics namespace or device, in case of an all paths down (APD) or permanent device loss (PDL) failure, the datastore might be inaccessible even after recovery. You cannot access the datastore from either the ESXi host or the vCenter Server system.

Workaround: To recover from this state, perform a rescan on a host or cluster level. For more information, see Perform Storage Rescan.

Deleted CNS volumes might temporarily appear as existing in the CNS UI

After you delete an FCD disk that backs a CNS volume, the volume might still show up as existing in the CNS UI. However, your attempts to delete the volume fail. You might see an error message similar to the following:

```
The object or item referred to could not be found.
```

Workaround: The next full synchronization will resolve the inconsistency and correctly update the CNS UI.

Attempts to attach multiple CNS volumes to the same pod might occasionally fail with an error

When you attach multiple volumes to the same pod simultaneously, the attach operation might occasionally choose the same controller slot. As a result, only one of the operations succeeds, while other volume mounts fail.

Workaround: After Kubernetes retries the failed operation, the operation succeeds if a controller slot is available on the node VM.

Under certain circumstances, while a CNS operation fails, the task status appears as successful in the vSphere Client

This might occur when, for example, you use an incompliant storage policy to create a CNS volume. The operation fails, while the vSphere Client shows the task status as successful.

Workaround: The successful task status in the vSphere Client does not guarantee that the CNS operation succeeded. To make sure the operation succeeded, verify its results.

Unsuccessful delete operation for a CNS persistent volume might leave the volume undeleted on the vSphere datastore

This issue might occur when the CNS Delete API attempts to delete a persistent volume that is still attached to a pod. For example, when you delete the Kubernetes namespace where the pod runs. As a result, the volume gets cleared from CNS and the CNS query operation does not return the volume. However, the volume continues to reside on the datastore and cannot be deleted through the repeated CNS Delete API operations.

Workaround: None.

vCenter Server and vSphere Client Issues

Vendor providers go offline after a PNID change

When you change the vCenter IP address (PNID change), the registered vendor providers go offline.

Workaround: Re-register the vendor providers.

Cross vCenter migration of a virtual machine fails with an error

When you use cross vCenter vMotion to move a VM's storage and host to a different vCenter server instance, you might receive the error `The operation is not allowed in the current state.`

This error appears in the UI wizard after the Host Selection step and before the Datastore Selection step, in cases where the VM has an assigned storage policy containing host-based rules such as encryption or any other IO filter rule.

Workaround: Assign the VM and its disks to a storage policy without host-based rules. You might need to decrypt the VM if the source VM is encrypted. Then retry the cross vCenter vMotion action.

Storage Sensors information in Hardware Health tab shows incorrect values on vCenter UI, host UI, and MOB

When you navigate to **Host > Monitor > Hardware Health > Storage Sensors** on vCenter UI, the storage information displays either incorrect or unknown values. The same issue is observed on the host UI and the MOB path `"runtime.hardwareStatusInfo.storageStatusInfo"` as well.

Workaround: None.

vSphere UI host advanced settings shows the current product locker location as empty with an empty default

vSphere UI host advanced settings shows the current product locker location as empty with an empty default. This is inconsistent as the actual product location `symlink` is created and valid. This causes confusion to the user. The default cannot be corrected from UI.

Workaround: User can use the esxcli command on the host to correct the current product locker location default as below.

1. Remove the existing Product Locker Location setting with: "`esxcli system settings advanced remove -o ProductLockerLocation`"

2. Re-add the Product Locker Location setting with the appropriate default:

2.a. If the ESXi is a full installation, the default value is "`/locker/packages/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/locker/packages/vmtoolsRepo`"

2.b. If the ESXi is a PXEboot configuration such as autodeploy, the default value is: "`/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/vmtoolsRepo`"

Run the following command to automatically figure out the location: `export PRODUCT_LOCKER_DEFAULT=`readlink /productLocker``

Add the setting: `esxcli system settings advanced add -d "Path to VMware Tools repository" -o ProductLockerLocation -t string -s $PRODUCT_LOCKER_DEFAULT`

You can combine all the above steps in step 2 by issuing the single command:

```
esxcli system settings advanced add -d "Path to VMware Tools repository" -o
ProductLockerLocation -t string -s `readlink /productLocker`
```

Linked Software-Defined Data Center (SDDC) vCenter Server instances appear in the on-premises vSphere Client if a vCenter Cloud Gateway is linked to the SDDC.

When a vCenter Cloud Gateway is deployed in the same environment as an on-premises vCenter Server, and linked to an SDDC, the SDDC vCenter Server will appear in the on-premises vSphere Client. This is unexpected behavior and the linked SDDC vCenter Server should be ignored. All operations involving the linked SDDC vCenter Server should be performed on the vSphere Client running within the vCenter Cloud Gateway.

Workaround: None.

Virtual Machine Management Issues

UEFI HTTP booting of virtual machines on ESXi hosts of version earlier than 7.0 Update 2 fails

UEFI HTTP booting of virtual machines is supported only on hosts of version ESXi 7.0 Update 2 and later and VMs with HW version 19 or later.

Workaround: Use UEFI HTTP booting only in virtual machines with HW version 19 or later. Using HW version 19 ensures the virtual machines are placed only on hosts with ESXi version 7.0 Update 2 or later.

Virtual machine snapshot operations fail in vSphere Virtual Volumes datastores on Purity version 5.3.10

Virtual machine snapshot operations fail in vSphere Virtual Volumes datastores on Purity version 5.3.10 with an error such as `An error occurred while saving the snapshot: The VVol target encountered a vendor specific error`. The issue is specific for Purity version 5.3.10.

Workaround: Upgrade to Purity version 6.1.7 or follow vendor recommendations.

The postcustomization section of the customization script runs before the guest customization

When you run the guest customization script for a Linux guest operating system, the `precustomization` section of the customization script that is defined in the customization specification runs before the guest customization and the `postcustomization` section runs after that. If you enable Cloud-Init in the guest operating system of a virtual machine, the `postcustomization` section runs before the customization due to a known issue in Cloud-Init.

Workaround: Disable Cloud-Init and use the standard guest customization.

Group migration operations in vSphere vMotion, Storage vMotion, and vMotion without shared storage fail with error

When you perform group migration operations on VMs with multiple disks and multi-level snapshots, the operations might fail with the error `com.vmware.vc.GenericVmConfigFault Failed waiting for data. Error 195887167. Connection closed by remote host, possibly due to timeout.`

Workaround: Retry the migration operation on the failed VMs one at a time.

Deploying an OVF or OVA template from a URL fails with a 403 Forbidden error

The URLs that contain an HTTP query parameter are not supported. For example, `http://webaddress.com?file=abc.ovf` or the Amazon pre-signed S3 URLs.

Workaround: Download the files and deploy them from your local file system.

The third level of nested objects in a virtual machine folder is not visible

Perform the following steps:

1. Navigate to a data center and create a virtual machine folder.
2. In the virtual machine folder, create a nested virtual machine folder.
3. In the second folder, create another nested virtual machine, virtual machine folder, vApp, or VM Template.

As a result, from the VMs and Templates inventory tree you cannot see the objects in the third nested folder.

Workaround: To see the objects in the third nested folder, navigate to the second nested folder and select the VMs tab.

vSphere HA and Fault Tolerance Issues

VMs in a cluster might be orphaned after recovering from storage inaccessibility such as a cluster wide APD

Some VMs might be in orphaned state after cluster wide APD recovers, even if HA and VMCP are enabled on the cluster.

This issue might be encountered when the following conditions occur simultaneously:

- All hosts in the cluster experience APD and do not recover until VMCP timeout is reached.
- HA primary initiates failover due to APD on a host.
- Power on API during HA failover fails due to one of the following:
  - APD across the same host
  - Cascading APD across the entire cluster
  - Storage issues
  - Resource unavailability
- FDM unregistration and VCs steal VM logic might initiate during a window where FDM has not unregistered the failed VM and VC's host synchronization responds that multiple hosts are reporting the same VM. Both FDM and VC unregister the different registered copies of the same VM from different hosts, causing the VM to be orphaned.

Workaround: You must unregister and reregister the orphaned VMs manually within the cluster after the APD recovers.

If you do not manually reregister the orphaned VMs, HA attempts failover of the orphaned VMs, but it might take between 5 to 10 hours depending on when APD recovers.

The overall functionality of the cluster is not affected in these cases and HA will continue to protect the VMs. This is an anomaly in what gets displayed on VC for the duration of the problem.

vSphere Lifecycle Manager Issues

vSphere Lifecycle Manager and vSAN File Services cannot be simultaneously enabled on a vSAN cluster in vSphere 7.0 release

If vSphere Lifecycle Manager is enabled on a cluster, vSAN File Services cannot be enabled on the same cluster and vice versa. In order to enable vSphere Lifecycle Manager on a cluster, which has VSAN File Services enabled already, first

disable vSAN File Services and retry the operation. Please note that if you transition to a cluster that is managed by a single image, vSphere Lifecycle Manager cannot be disabled on that cluster.

Workaround: None.

When a hardware support manager is unavailable, vSphere High Availability (HA) functionality is impacted

If hardware support manager is unavailable for a cluster that you manage with a single image, where a firmware and drivers addon is selected and vSphere HA is enabled, the vSphere HA functionality is impacted. You may experience the following errors.

- Configuring vSphere HA on a cluster fails.
- Cannot complete the configuration of the vSphere HA agent on a host: `Applying HA VIBs on the cluster encountered a failure.`
- Remediating vSphere HA fails: `A general system error occurred: Failed to get Effective Component map.`
- Disabling vSphere HA fails: Delete Solution task failed. `A general system error occurred: Cannot find hardware support package from depot or hardware support manager.`

Workaround:

- If the hardware support manager is temporarily unavailable, perform the following steps.

1. Reconnect the hardware support manager to vCenter Server.
2. Select a cluster from the Hosts and Cluster menu.
3. Select the Configure tab.
4. Under Services, click vSphere Availability.
5. Re-enable vSphere HA.

- If the hardware support manager is permanently unavailable, perform the following steps.

1. Remove the hardware support manager and the hardware support package from the image specification
2. Re-enable vSphere HA.
3. Select a cluster from the Hosts and Cluster menu.
4. Select the Updates tab.
5. Click Edit .
6. Remove the firmware and drivers addon and click Save.
7. Select the Configure tab.
8. Under Services, click vSphere Availability.
9. Re-enable vSphere HA.

I/OFilter is not removed from a cluster after a remediation process in vSphere Lifecycle Manager

Removing I/OFilter from a cluster by remediating the cluster in vSphere Lifecycle Manager, fails with the following error message: `iofilter XXX already exists` . The iofilter remains listed as installed.

Workaround:

1. Call IOFilter API `UninstallIoFilter_Task` from the vCenter Server managed object (IoFilterManager).
2. Remediate the cluster in vSphere Lifecycle Manager.
3. Call IOFilter API `ResolveInstallationErrorsOnCluster_Task` from the vCenter Server managed object (IoFilterManager) to update the database.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, adding hosts causes a vSphere HA error state

Adding one or multiple ESXi hosts during a remediation process of a vSphere HA enabled cluster, results in the following error message: `Applying HA VIBs on the cluster encountered a failure.`

Workaround: After the cluster remediation operation has finished, perform one of the following tasks.

- Right-click the failed ESXi host and select *Reconfigure for vSphere HA*.
- Disable and re-enable vSphere HA for the cluster.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, disabling and re-enabling vSphere HA causes a vSphere HA error state

Disabling and re-enabling vSphere HA during remediation process of a cluster, may fail the remediation process due to vSphere HA health checks reporting that hosts don't have vSphere HA VIBs installed. You may see the following error message: `Setting desired image spec for cluster failed.`

Workaround: After the cluster remediation operation has finished, disable and re-enable vSphere HA for the cluster.

Checking for recommended images in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the recommendation generation task could take more than an hour to finish or may appear to hang. The completion time for the recommendation task depends on the number of devices configured on each host and the number of image candidates from the depot that vSphere Lifecycle Manager needs to process before obtaining a valid image to recommend.

Workaround: None.

Checking for hardware compatibility in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the validation report generation task could take up to 30 minutes to finish or may appear to hang. The completion time depends on the number of devices configured on each host and the number of hosts configured in the cluster.

Workaround: None

Incomplete error messages in non-English languages are displayed, when remediating a cluster in vSphere Lifecycle Manager

You can encounter incomplete error messages for localized languages in the vCenter Server user interface. The messages are displayed, after a cluster remediation process in vSphere Lifecycle Manager fails. For example, your can observe the following error message.

The error message in English language: `Virtual machine 'VMC on DELL EMC -FileServer' that runs on cluster 'Cluster-1' reported an issue which prevents entering maintenance mode: Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

The error message in French language: `La VM « VMC on DELL EMC -FileServer », située sur le cluster « {Cluster-1} », a signalé un problème empêchant le passage en mode de maintenance : Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

Workaround: None.

Importing an image with no vendor addon, components, or firmware and drivers addon to a cluster which image contains such elements, does not remove the image elements of the existing image

Only the ESXi base image is replaced with the one from the imported image.

Workaround: After the import process finishes, edit the image, and if needed, remove the vendor addon, components, and firmware and drivers addon.

When you convert a cluster that uses baselines to a cluster that uses a single image, a warning is displayed that vSphere HA VIBs will be removed

Converting a vSphere HA enabled cluster that uses baselines to a cluster that uses a single image, may result a warning message displaying that `vmware-fdm` component will be removed.

Workaround: This message can be ignored. The conversion process installs the `vmware-fdm` component.

If vSphere Update Manager is configured to download patch updates from the Internet through a proxy server, after upgrade to vSphere 7.0 that converts Update Manager to vSphere Lifecycle Manager, downloading patches from VMware patch repository might fail

In earlier releases of vCenter Server you could configure independent proxy settings for vCenter Server and vSphere Update Manager. After an upgrade to vSphere 7.0, vSphere Update Manager service becomes part of the vSphere Lifecycle Manager service. For the vSphere Lifecycle Manager service, the proxy settings are configured from the vCenter Server appliance settings. If you had configured Update Manager to download patch updates from the Internet through a proxy server but the vCenter Server appliance had no proxy setting configuration, after a vCenter Server upgrade to version 7.0, the vSphere Lifecycle Manager fails to connect to the VMware depot and is unable to download patches or updates.

Workaround: Log in to the vCenter Server Appliance Management Interface, https://*vcenter-server-appliance-FQDN-or-IP-address*:5480, to configure proxy settings for the vCenter Server appliance and enable vSphere Lifecycle Manager to use proxy.

Miscellaneous Issues

When applying a host profile with version 6.5 to a ESXi host with version 7.0, the compliance check fails

Applying a host profile with version 6.5 to a ESXi host with version 7.0, results in Coredump file profile reported as not compliant with the host.

Workaround: There are two possible workarounds.

1. When you create a host profile with version 6.5, set an advanced configuration option VMkernel.Boot.autoCreateDumpFile to false on the ESXi host.
2. When you apply an existing host profile with version 6.5, add an advanced configuration option VMkernel.Boot.autoCreateDumpFile in the host profile, configure the option to a fixed policy, and set value to false.

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit minor throughput degradation when Dynamic Receive Side Scaling (DYN_RSS) or Generic RSS (GEN_RSS) feature is turned on

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit less than 5 percent throughput degradation when DYN_RSS and GEN_RSS feature is turned on, which is unlikely to impact normal workloads.

Workaround: You can disable DYN_RSS and GEN_RSS feature with the following commands:

```
# esxcli system module parameters set -m nmlx5_core -p "DYN_RSS=0 GEN_RSS=0"
# reboot
```

RDMA traffic between two VMs on the same host might fail in PVRDMA environment

In a vSphere 7.0 implementation of a PVRDMA environment, VMs pass traffic through the HCA for local communication if an HCA is present. However, loopback of RDMA traffic does not work on qedrntv driver. For instance, RDMA Queue Pairs running on VMs that are configured under same uplink port cannot communicate with each other.

In vSphere 6.7 and earlier, HCA was used for local RDMA traffic if SRQ was enabled. vSphere 7.0 uses HCA loopback with VMs using versions of PVRDMA that have SRQ enabled with a minimum of HW v14 using RoCE v2.

The current version of Marvell FastLinQ adapter firmware does not support loopback traffic between QPs of the same PF or port.

Workaround: Required support is being added in the out-of-box driver certified for vSphere 7.0. If you are using the inbox qedrntv driver, you must use a 3-host configuration and migrate VMs to the third host.

Unreliable Datagram traffic QP limitations in qedrntv driver

There are limitations with the Marvell FastLinQ qedrntv RoCE driver and Unreliable Datagram (UD) traffic. UD applications involving bulk traffic might fail with qedrntv driver. Additionally, UD QPs can only work with DMA Memory Regions (MR). Physical MRs or FRMR are not supported. Applications attempting to use physical MR or FRMR along with UD QP fail to pass traffic when used with qedrntv driver. Known examples of such test applications are `ibv_ud_pingpong` and `ib_send_bw`.

Standard RoCE and RoCEv2 use cases in a VMware ESXi environment such as iSER, NVMe-oF (RoCE) and PVRDMA are not impacted by this issue. Use cases for UD traffic are limited and this issue impacts a small set of applications requiring bulk UD traffic.

Marvell FastLinQ hardware does not support RDMA UD traffic offload. In order to meet the VMware PVRDMA requirement to support GSI QP, a restricted software only implementation of UD QP support was added to the qedrntv driver. The goal of the implementation is to provide support for control path GSI communication and is not a complete implementation of UD QP supporting bulk traffic and advanced features.

Since UD support is implemented in software, the implementation might not keep up with heavy traffic and packets might be dropped. This can result in failures with bulk UD traffic.

Workaround: Bulk UD QP traffic is not supported with qedrntv driver and there is no workaround at this time. VMware ESXi RDMA (RoCE) use cases like iSER, NVMe, RDMA and PVRDMA are unaffected by this issue.

Servers equipped with QLogic 578xx NIC might fail when frequently connecting or disconnecting iSCSI LUNs

If you trigger QLogic 578xx NIC iSCSI connection or disconnection frequently in a short time, the server might fail due to an issue with the qfle3 driver. This is caused by a known defect in the device's firmware.

Workaround: None.

ESXi might fail during driver unload or controller disconnect operation in Broadcom NVMe over FC environment

In Broadcom NVMe over FC environment, ESXi might fail during driver unload or controller disconnect operation and display an error message such as: `@BlueScreen: #PF Exception 14 in world 2098707:vmknvmeGener IP 0x4200225021cc addr 0x19`

Workaround: None.

ESXi does not display OEM firmware version number of i350/X550 NICs on some Dell servers

The inbox ixgben driver only recognizes firmware data version or signature for i350/X550 NICs. On some Dell servers the OEM firmware version number is programmed into the OEM package version region, and the inbox ixgben driver does not read this information. Only the 8-digit firmware signature is displayed.

Workaround: To display the OEM firmware version number, install async ixgben driver version 1.7.15 or later.

X710 or XL710 NICs might fail in ESXi

When you initiate certain destructive operations to X710 or XL710 NICs, such as resetting the NIC or manipulating VMKernel's internal device tree, the NIC hardware might read data from non-packet memory.

Workaround: Do not reset the NIC or manipulate vmkernel internal device state.

NVMe-oF does not guarantee persistent VMHBA name after system reboot

NVMe-oF is a new feature in vSphere 7.0. If your server has a USB storage installation that uses vmhba30+ and also has NVMe over RDMA configuration, the VMHBA name might change after a system reboot. This is because the VMHBA name assignment for NVMe over RDMA is different from PCIe devices. ESXi does not guarantee persistence.

Workaround: None.

Backup fails for vCenter database size of 300 GB or greater

If the vCenter database size is 300 GB or greater, the file-based backup will fail with a timeout. The following error message is displayed: `Timeout! Failed to complete in 72000 seconds`

Workaround: None.

A restore of vCenter Server 7.0 which is upgraded from vCenter Server 6.x with External Platform Services Controller to vCenter Server 7.0 might fail

When you restore a vCenter Server 7.0 which is upgraded from 6.x with External Platform Services Controller to vCenter Server 7.0, the restore might fail and display the following error: `Failed to retrieve appliance storage list`

Workaround: During the first stage of the restore process, increase the storage level of the vCenter Server 7.0. For example if the vCenter Server 6.7 External Platform Services Controller setup storage type is small, select storage type large for the restore process.

Enabled SSL protocols configuration parameter is not configured during a host profile remediation process

`Enabled SSL protocols` configuration parameter is not configured during a host profile remediation and only the system default protocol `tlsv1.2` is enabled. This behavior is observed for a host profile with version 7.0 and earlier in a vCenter Server 7.0 environment.

Workaround: To enable TLSV 1.0 or TLSV 1.1 SSL protocols for SFCB, log in to an ESXi host by using SSH, and run the following ESXCLI command: `esxcli system wbem -P <protocol_name>`

Unable to configure Lockdown Mode settings by using Host Profiles

Lockdown Mode cannot be configured by using a security host profile and cannot be applied to multiple ESXi hosts at once. You must manually configure each host.

Workaround: In vCenter Server 7.0, you can configure Lockdown Mode and manage Lockdown Mode exception user list by using a security host profile.

When a host profile is applied to a cluster, Enhanced vMotion Compatibility (EVC) settings are missing from the ESXi hosts

Some settings in the VMware config file `/etc/vmware/config` are not managed by Host Profiles and are blocked, when the config file is modified. As a result, when the host profile is applied to a cluster, the EVC settings are lost, which causes loss of EVC functionalities. For example, unmasked CPUs can be exposed to workloads.

Workaround: Reconfigure the relevant EVC baseline on cluster to recover the EVC settings.

Using a host profile that defines a core dump partition in vCenter Server 7.0 results in an error

In vCenter Server 7.0, configuring and managing a core dump partition in a host profile is not available. Attempting to apply a host profile that defines a core dump partition, results in the following error: `No valid coredump partition found.`

Workaround: None. In vCenter Server 7.0., Host Profiles supports only file-based core dumps.

If you run the ESXCLI command to unload the firewall module, the hostd service fails and ESXi hosts lose connectivity

If you automate the firewall configuration in an environment that includes multiple ESXi hosts, and run the ESXCLI command `esxcli network firewall unload` that destroys filters and unloads the firewall module, the hostd service fails and ESXi hosts lose connectivity.

Workaround: Unloading the firewall module is not recommended at any time. If you must unload the firewall module, use the following steps:

1. Stop the hostd service by using the command:
   `/etc/init.d/hostd stop.`
2. Unload the firewall module by using the command:
   `esxcli network firewall unload.`
3. Perform the required operations.
4. Load the firewall module by using the command:
   `esxcli network firewall load.`
5. Start the hostd service by using the command:
   `/etc/init.d/hostd start.`

vSphere Storage vMotion operations might fail in a vSAN environment due to an unauthenticated session of the Network File Copy (NFC) manager

Migrations to a vSAN datastore by using vSphere Storage vMotion of virtual machines that have at least one snapshot and more than one virtual disk with different storage policy might fail. The issue occurs due to an unauthenticated session of the NFC manager because the Simple Object Access Protocol (SOAP) body exceeds the allowed size.

Workaround: First migrate the VM home namespace and just one of the virtual disks. After the operation completes, perform a disk only migration of the remaining 2 disks.

Changes in the properties and attributes of the devices and storage on an ESXi host might not persist after a reboot

If the device discovery routine during a reboot of an ESXi host times out, the jumpstart plug-in might not receive all configuration changes of the devices and storage from all the registered devices on the host. As a result, the process might restore the properties of some devices or storage to the default values after the reboot.

Workaround: Manually restore the changes in the properties of the affected device or storage.

If you use a beta build of ESXi 7.0, ESXi hosts might fail with a purple diagnostic screen during some lifecycle operations

If you use a beta build of ESXi 7.0, ESXi hosts might fail with a purple diagnostic screen during some lifecycle operations such as unloading a driver or switching between ENS mode and native driver mode. For example, if you try to change the ENS mode, in the backtrace you see an error message similar to: `case ENS::INTERRUPT::NoVM_DeviceStateWithGracefulRemove hit BlueScreen: ASSERT bora/vmkernel/main/dlmalloc.c:2733` This issue is specific for beta builds and does not affect release builds such as ESXi 7.0.

Workaround: Update to ESXi 7.0 GA.

You cannot create snapshots of virtual machines due to an error that a digest operation has failed

A rare race condition when an All-Paths-Down (APD) state occurs during the update of the Content Based Read Cache (CBRC) digest file might cause inconsistencies in the digest file. As a result, you cannot create virtual machine snapshots. You see an error such as `An error occurred while saving the snapshot: A digest operation has failed` in the backtrace.

Workaround: Power cycle the virtual machines to trigger a recompute of the CBRC hashes and clear the inconsistencies in the digest file.

If you upgrade your ESXi hosts to version 7.0 Update 3, but your vCenter Server is of an earlier version, Trusted Platform Module (TPM) attestation of the ESXi hosts fails

If you upgrade your ESXi hosts to version 7.0 Update 3, but your vCenter Server is of an earlier version, and you enable TPM, ESXi hosts fail to pass attestation. In the vSphere Client, you see the warning Host TPM attestation alarm. The Elliptic Curve Digital Signature Algorithm (ECDSA) introduced with ESXi 7.0 Update 3 causes the issue when vCenter Server is not of version 7.0 Update 3.

Workaround: Upgrade your vCenter Server to 7.0 Update 3 or acknowledge the alarm.

You see warnings in the boot loader screen about TPM asset tags

If a TPM-enabled ESXi host has no asset tag set on, you might see idle warning messages in the boot loader screen such as:

```
Failed to determine TPM asset tag size: Buffer too smallFailed to measure asset tag into TPM: Buffer too small
```

Workaround: Ignore the warnings or set an asset tag by using the command `$ esxcli hardware tpm tag set -d`

The sensord daemon fails to report ESXi host hardware status

A logic error in the IPMI SDR validation might cause `sensord` to fail to identify a source for power supply information. As a result, when you run the command `vsish -e get /power/hostStats`, you might not see any output.

Workaround: None

If an ESXi host fails with a purple diagnostic screen, the netdump service might stop working

In rare cases, if an ESXi host fails with a purple diagnostic screen, the netdump service might fail with an error such as `NetDump FAILED: Couldn't attach to dump server at IP x.x.x.x.`

Workaround: Configure the VMkernel core dump to use local storage.

You see frequent VMware Fault Domain Manager (FDM) core dumps on multiple ESXi hosts

In some environments, the number of datastores might exceed the FDM file descriptor limit. As a result, you see frequent core dumps on multiple ESXi hosts indicating FDM failure.

Workaround: Increase the FDM file descriptor limit to 2048. You can use the setting `das.config.fdm.maxFds` from the vSphere HA advanced options in the vSphere Client. For more information, see Set Advanced Options.

Virtual machines on a vSAN cluster with enabled NSX-T and a converged vSphere Distributed Switch (CVDS) in a VLAN transport zone cannot power on after a power off

If a secondary site is 95% disk full and VMs are powered off before simulating a secondary site failure, during recovery some of the virtual machines fail to power on. As a result, virtual machines become unresponsive. The issue occurs regardless if site recovery includes adding disks or ESXi hosts or CPU capacity.

Workaround: Select the virtual machines that do not power on and change the network to VM Network from Edit Settings on the VM context menu.

ESXI hosts might fail with a purple diagnostic screen with an error Assert at bora/modules/vmkernel/vmfs/fs6Journal.c:835

In rare cases, for example when running SESparse tests, the number of locks per transaction in a VMFS datastore might exceed the limit of 50 for the `J6_MAX_TXN_LOCKACTIONS` parameter. As a result, ESXi hosts might fail with a purple diagnostic screen with an error `Assert at bora/modules/vmkernel/vmfs/fs6Journal.c:835`.

Workaround: None

If you modify the netq_rss_ens parameter of the nmlx5_core driver, ESXi hosts might fail with a purple diagnostic screen

If you try to enable the `netq_rss_ens` parameter when you configure an enhanced data path on the `nmlx5_core` driver, ESXi hosts might fail with a purple diagnostic screen. The `netq_rss_ens` parameter, which enables NetQ RSS, is disabled by default with a value of `0`.

Workaround: Keep the default value for the `netq_rss_ens` module parameter in the `nmlx5_core` driver.

ESXi might terminate I/O to NVMeOF devices due to errors on all active paths

Occasionally, all active paths to NVMeOF device register I/O errors due to link issues or controller state. If the status of one of the paths changes to Dead, the High Performance Plug-in (HPP) might not select another path if it shows high volume of errors. As a result, the I/O fails.

Workaround: Disable the configuration option **/Misc/HppManageDegradedPaths** to unblock the I/O.

Upgrade to ESXi 7.0 Update 3 might fail due to changed name of the inbox i40enu network driver

Starting with vSphere 7.0 Update 3, the inbox i40enu network driver for ESXi changes name back to i40en. The i40en driver was renamed to i40enu in vSphere 7.0 Update 2, but the name change impacted some upgrade paths. For example, rollup upgrade of ESXi hosts that you manage with baselines and baseline groups from 7.0 Update 2 or 7.0 Update 2a to 7.0 Update 3 fails. In most cases, the i40enu driver upgrades to ESXi 7.0 Update 3 without any additional steps. However, if the driver upgrade fails, you cannot update ESXi hosts that you manage with baselines and baseline groups. You also cannot use host seeding or a vSphere Lifecycle Manager single image to manage the ESXi hosts. If you have already made changes related to the i40enu driver and devices in your system, before upgrading to ESXi 7.0 Update 3, you must uninstall the i40enu VIB or Component on ESXi, or first upgrade ESXi to ESXi 7.0 Update 2c.

Workaround: For more information, see VMware knowledge base article 85982.

SSH access fails after you upgrade to ESXi 7.0 Update 3d

After you upgrade to ESXi 7.0 Update 3d, SSH access might fail in certain conditions due to an update of OpenSSH to version 8.8.

Workaround: For more information, see VMware knowledge base article 88055.

USB device passthrough from ESXi hosts to virtual machines might fail

A USB modem device might simultaneously claim multiple interfaces by the VMkernel and block the device passthrough to VMs.

Workaround: You must apply the USB.quirks advanced configuration on the ESXi host to ignore the NET interface from VMkernel and allow the USB modem to passthrough to VMs. You can apply the configuration in 3 alternative ways:

1. Access the ESXi shell and run the following command: `esxcli system settings advanced set -o /USB/quirks -s 0xvvvv:0xpppp:0:0xffff:UQ_NET_IGNORE | |- Device Product ID |------- Device Vendor ID`
   For example, for the Gemalto M2M GmbH Zoom 4625 Modem(`vid:pid/1e2d:005b`), you can have the command `esxcli system settings advanced set -o /USB/quirks -s 0x1e2d:0x005b:0:0xffff:UQ_NET_IGNORE`
   Reboot the ESXi host.

2. Set the advanced configuration from the vSphere Client or the vSphere Web Client and reboot the ESXi host.
3. Use a Host Profile to apply the advanced configuration.

For more information on the steps, see VMware knowledge base article 80416.

HTTP requests from certain libraries to vSphere might be rejected

The HTTP reverse proxy in vSphere 7.0 enforces stricter standard compliance than in previous releases. This might expose pre-existing problems in some third-party libraries used by applications for SOAP calls to vSphere.

If you develop vSphere applications that use such libraries or include applications that rely on such libraries in your vSphere stack, you might experience connection issues when these libraries send HTTP requests to VMOMI. For example, HTTP requests issued from vijava libraries can take the following form:

```
POST /sdk HTTP/1.1
SOAPAction
Content-Type: text/xml; charset=utf-8
User-Agent: Java/1.8.0_221
```

The syntax in this example violates an HTTP protocol header field requirement that mandates a colon after SOAPAction. Hence, the request is rejected in flight.

Workaround: Developers leveraging noncompliant libraries in their applications can consider using a library that follows HTTP standards instead. For example, developers who use the vijava library can consider using the latest version of the yavijava library instead.

You might see a dump file when using Broadcom driver lsi_msgpt3, lsi_msgpt35 and lsi_mr3

When using the lsi_msgpt3, lsi_msgpt35 and lsi_mr3 controllers, there is a potential risk to see dump file lsuv2-lsi-drivers-plugin-util-zdump. There is an issue when exiting the storelib used in this plugin utility. There is no impact on ESXi operations, you can ignore the dump file.

Workaround: You can safely ignore this message. You can remove the lsuv2-lsi-drivers-plugin with the following command:

```
esxcli software vib remove -n lsuv2-lsiv2-drivers-plugin
```

You might see reboot is not required after configuring SR-IOV of a PCI device in vCenter, but device configurations made by third party extensions might be lost and require reboot to be re-applied.

In ESXi 7.0, SR-IOV configuration is applied without a reboot and the device driver is reloaded. ESXi hosts might have third party extensions perform device configurations that need to run after the device driver is loaded during boot. A reboot is required for those third party extensions to re-apply the device configuration.

Workaround: You must reboot after configuring SR-IOV to apply third party device configurations.

vSphere Client Issues

BIOS manufacturer displays as "--" in the vSphere Client

In the vSphere Client, when you select an ESXi host and navigate to **Configure** > **Hardware** > **Firmware**, you see `--` instead of the BIOS manufacturer name.

Workaround: For more information, see VMware knowledge base article 88937.

vSAN Issues

PR 2962316: vSAN File Service does not support NFSv4 delegations

vSAN File Service does not support NFSv4 delegations in this release.

Workaround: None

When rebooting a vSAN host, other hosts in the vSAN cluster enter a partitioned state

During ESXi shutdown, hosts in a vSAN cluster can enter a state where they can transmit but not receive data. Depending of the exact timing and duration of this state, this state can lead to unexpected role changes in the vSAN distributed cluster membership, monitoring, and directory service (CMMDS). Consequently, vSAN hosts might continually attempt to reform a cluster with the rebooting host or send CMMDS updates through the rebooting host, which is unresponsive to incoming traffic. As a result, in the vSAN Health monitoring you see `vSAN Cluster Partition` alarms.

Workaround: Before rebooting a vSAN host, identify all vmknics on the host with tags `VSAN` , `VSANWitness` , or `VSANExternal` , take note of which vSAN tag is used on each vmknic, and remove the tags. After rebooting, reapply the tags for vSAN traffic by type and vmknic.

PR 3235496: Applications on a vSAN cluster become intermittently unresponsive

If the advanced option `preferHT` is enabled on an AMD server in a vSAN cluster, the virtual CPUs of a virtual machine run on the same last level cache. When the virtual CPUs are all very busy and an NVMe thread to handle I/Os happens to run also on the same last level cache, the NVMe thread takes very long to complete, because it competes for CPU resources with the busy VMs. As a result, the I/O latency is very high and might lead to intermittent unresponsiveness of storage and applications on the vSAN cluster. In the backlog, you see errors such as `Lost access to volume <uuid> due to connectivity issues. Recovery attempt is in progress and outcome will be reported shortly.`

Workaround: Use the command `esxcli system settings advanced set -o /Misc/vmknvmeCwYield -I 0` to avoid competition between the NVMe completion queue and busy virtual CPUs.

VMware ESXi 7.0 Update 3v Release Notes

This document contains the following sections

- Introduction
- What's New
- Patches Contained in This Release
- Patch Download and Installation
- Resolved Issues
- Known Issues
- Known Issues from Previous Releases

Introduction

VMware ESXi 7.0 Update 3v | 20 MAY 2025 | Build 24723872 Check for additions and updates to these release notes.

IMPORTANT: If your source system contains hosts of versions between ESXi 7.0 Update 2 and Update 3c, and Intel drivers, before upgrading to ESXi 7.0 Update 3v, see the What's New section of the VMware vCenter Server 7.0 Update 3c Release Notes, because all content in the section is also applicable for vSphere 7.0 Update 3v. Also, see the related VMware knowledge base articles: 86447, 87258, and 87308.

What's New

This release resolves CVE-2025-41226, CVE-2025-41227, and CVE-2025-41228. For more information on these vulnerabilities and their impact on Broadcom products, see VMSA-2025-0010.

ESXi 7.0 Update 3v adds support for vSphere Quick Boot to the following:

Drivers:

- AMD
  - AMD Instinct MI Series Driver
- Intel
  - Intel vRAN Baseband Driver
  - Intel Platform Monitoring Technology Driver
  - Intel Data Center Graphics Driver

Servers

- CISCO
  - UCSC-C240-M7SX
  - UCSC-C245-M8SX
- HPE
  - HPE Alletra Storage Server 4120
  - HPE ProLiant DL145 Gen11
- Supermicro
  - AS-2025HS-TNR

Patches Contained in This Release

This release of ESXi 7.0 Update 3v delivers the following patches:

Build Details

Download Filename:	VMware-ESXi-7.0U3v-24723872-depot.zip
Build:	24723872
Download Size:	585 MB

sha256checksum:	b9402fd4152cfd79a5e019c5445e83991f96d67b9718290a0aa45f224a3ab997
Host Reboot Required:	Yes
Virtual Machine Migration or Shutdown Required:	Yes

Components

Component	Bulletin	Category	Severity
ESXi Component - core ESXi VIBs	ESXi_7.0.3-0.145.24723872	Bugfix	Critical
ESXi Install/Upgrade Component	esx-update_7.0.3-0.145.24723872	Bugfix	Critical
Broadcom NetXtreme I ESX VMKAPI ethernet driver	Broadcom-ntg3_4.1.15.0-4vmw.703.0.145.24723872	Bugfix	Critical
VMware NVMe over TCP Driver	VMware-NVMeoF-TCP_1.0.0.7-1vmw.703.0.145.24723872	Bugfix	Critical

Component	Bulletin	Category	Severity
ESXi Component - core ESXi VIBs	ESXi_7.0.3-0.140.24723868	Security	Critical
ESXi Install/Upgrade Component	esx-update_7.0.3-0.140.24723868	Security	Critical
ESXi Tools Component	VMware-VM-Tools_12.5.1.24649672-24723868	Security	Critical

IMPORTANT:

- Starting with vSphere 7.0, VMware uses components for packaging VIBs along with bulletins. The `ESXi` and `esx-update` bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.
- When patching ESXi hosts by using VMware Update Manager from a version prior to ESXi 7.0 Update 2, it is strongly recommended to use the rollup bulletin in the patch baseline. If you cannot use the rollup bulletin, be sure to include *all* of the following packages in the patching baseline. If the following packages are not included in the baseline, the update operation fails:
  - VMware-vmkusb_0.1-1vmw.701.0.0.16850804 or higher
  - VMware-vmkata_0.1-1vmw.701.0.0.16850804 or higher
  - VMware-vmkfcoe_1.0.0.2-1vmw.701.0.0.16850804 or higher
  - VMware-NVMeoF-RDMA_1.0.1.2-1vmw.701.0.0.16850804 or higher

Rollup Bulletin

This rollup bulletin contains the latest VIBs with all the fixes after the initial release of ESXi 7.0.

Bulletin ID	Category	Severity	Details
ESXi70U3v-24723872	Bugfix	Critical	Security and Bugfix
ESXi70U3sv-24723868	Security	Critical	Security only

Image Profiles

VMware patch and update releases contain general and critical image profiles. Application of the general release image profile applies to new bug fixes.

Image Profile Name
ESXi-7.0U3v-24723872-standard
ESXi-7.0U3v-24723872-no-tools
ESXi-7.0U3sv-24723868-standard
ESXi-7.0U3sv-24723868-no-tools

ESXi Image

Name and Version	Release Date	Category	Details
ESXi 7.0 U3v - 24723872	MAY 20 2025	Bugfix	Security and Bugfix
ESXi 7.0 U3sv - 24723868	MAY 20 2025	Security	Security only

Patch Download and Installation

Log in to the Broadcom Support Portal to download this patch.

See these KBs for details on the authenticated online and offline download: 390121, 390098, and 389276.

In vSphere 7.x, the Update Manager plug-in, used for administering vSphere Update Manager, is replaced with the Lifecycle Manager plug-in. Administrative operations for vSphere Update Manager are still available under the Lifecycle Manager plug-in, along with new capabilities for vSphere Lifecycle Manager.

The typical way to apply patches to ESXi 7.x hosts is by using the vSphere Lifecycle Manager. For details, see About vSphere Lifecycle Manager and vSphere Lifecycle Manager Baselines and Images.

You can also update ESXi hosts without using the Lifecycle Manager plug-in, and use an image profile instead. To do this, you must manually download the patch offline bundle ZIP file.

For details, see Upgrading Hosts by Using ESXCLI Commands, and the VMware ESXi Upgrade guide.

Resolved Issues

The resolved issues are grouped as follows:

ESXi_7.0.3-0.145.24723872

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A

CVE numbers	CVE-2025-41226, CVE-2025-41227, CVE-2025-41228

The ESXi and esx-update bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.

This patch updates the `native-misc-drivers, vsan, bmcal, esx-xserver, gc, esx-base, esxio-combiner, trx, cpu-microcode, esx-dvfilter-generic-fastpath, vsanhealth, crx` , and `vdfs` VIBs to resolve the following issues:

PR 3406033: ESXi host fails with a purple diagnostic screen due to a rare physical CPU (PCPU) lockup

In the vSphere Client, when you use the **Delete from Disk** option to remove a virtual machine from a vCenter system and delete all VM files from the datastore, including the configuration file and virtual disk files, if any of the files is corrupted, a rare issue with handling corrupted files in the delete path might lead to a PCPU lockup. As a result, the ESXi host fails with a purple diagnostic screen and a message such as `NMI IPI: Panic requested by another PCPU.`

This issue is resolved in this release.

PR 3484786: ESXi installation on an iSCSI LUN fails as the ESXi iSCSI Boot Firmware Table (iBFT) module fails to discover the LUN

In some cases, the iBFT control structure might have an optional expansion for which the ESXi vmkibft module doesn't have a proper check. As a result, iSCSI LUN discovery by using iBFT might fail and cause failure of the ESXi installation on the iSCSI LUN.

This issue is resolved in this release.

PR 3423217: You see vendor name of some Solidigm NVMe devices as Unknown

In the ESXi Host Client, under **Manage > Hardware > PCI Devices**, and in the vSphere Client, under **Host > Configure > Hardware > PCI Devices > All PCI Devices**, you might see the vendor name of some Solidigm NVMe devices as `Unknown.`

This issue is resolved in this release.

PR 3398537: ESXi host fails with a purple diagnostic screen due to an I/O race with an error PSOD @BlueScreen: ASSERT bora/lib/misc/bitvector.c:632

Due to a rare I/O race condition on virtual machines backed by a vSphere Virtual Volume, the ESXi host might fail with a purple diagnostic screen and an error such as `PSOD @BlueScreen: ASSERT bora/lib/misc/bitvector.c:632.`

This issue is resolved in this release.

PR 3371201: The hostd service might generate core dumps during upgrade from ESXi 6.7 to 7.x when SNMP traps are configured

In very rare cases, a missing SNMP port value when SNMP traps are configured during an upgrade from ESXi 6.7 to 7.x, might lead to hostd core dumps.

This issue is resolved in this release.

PR 3352051: Syslog configuration changes in a host profile that you use to provision ESXi host with Auto Deploy stateful install do not persist across reboots

If you change the syslog configuration of a host profile and provision ESXi hosts with that profile by using the Auto Deploy stateful install, changes might not persist after the hosts reboot.

This issue is resolved in this release.

PR 3396010: Controller VMs with direct I/O devices in third-party hyper converged infrastructure environments experience guest kernel soft lockups

A rare race condition between the interrupt virtualization and the VMkernel CPU scheduler in an ESXi host might result in guest kernel soft lockups on controller VMs with direct I/O devices in third-party hyper converged infrastructure environments. The soft locks cause virtual machines in the entire cluster to lose NFS storage connectivity and I/O access.

This issue is resolved in this release.

PR 3359386: If the Latency Sensitivity parameter of a virtual machine is set to High, you cannot add memory to that VM when powered off

If you use the vSphere Client to set the `Latency Sensitivity` parameter of a VM to `High` , attempts to add memory to such a VM when powered off might fail with an error such as `A specified parameter was not correct: spec.memoryAllocation` .

This issue is resolved in this release.

PR 3403867: Setting the CPU limit to 0 makes virtual machines unresponsive

If for any reason you set the CPU limit of running virtual machines to `0` , this causes CPU starvation and the VMs become unresponsive.

This issue is resolved in this release.

PR 3457552: You might see multiple hardware sensor alerts due to a Baseboard Management Controller (BMC) issue

An underlying BMC issue might cause ESXi hardware health monitoring to produce multiple alerts for hardware sensors on ESXi hosts, which you see in the vSphere Client under **Monitor > Tasks and Events**.

This issue is resolved in this release. The fix logs raw sensor data directly from IPMI to provide a data point to debug possible BMC issues that cause false alerts but cannot prevent BMC issues from occuring.

PR 3484794: Restoring the iSCSI configurations on an ESXi host might fail during boot due to stale entries in the ConfigStore database

If the ConfigStore database on an ESXi host has stale iSCSI configurations related to hardware iSCSI adapters, the iSCSI jumpstart might fail and restoring the iSCSI configuration on that host also fails during boot.

This issue is resolved in this release.

PR 3484793: Discovery of iSCSI dynamic targets, LUNs, and datastores fails on ESXi host reboot

In some cases, dynamic discovery of targets in systems that use dynamic discovery addresses for iSCSI configuration might fail. As a result, you do not see iSCSI targets, LUNs, and datastores after a reboot of ESXi hosts. The dynamic discovery of iSCSI targets might also fail when the Challenge-Handshake Authentication Protocol (CHAP) is active on the ESXi host.

This issue is resolved in this release.

PR 3425364: Setting `cloud-init guestInfo` variables by regular users in the guest results into an error

Starting with ESXi 7.0 Update 3v, setting `cloud-init guestInfo` variables by regular users in the guest results into an error due to design changes.

This issue is resolved in this release. For more information, see KB 377267.

PR 3458283: A rare Baseboard Management Controller (BMC) issue might cause some applications to become unresponsive

If an application sends an IPMI request to the BMC while it resets, such requests remain indefinitely pending and cause the applications to become unresponsive.

This issue is resolved in this release. The fix updates the IPMI driver to handle such conditions.

PR 3485174: Guest OS might mark file system read-only after repeated I/O failure which can cause Kubernetes control plane nodes to go into Read-only mode

An issue with the check for max allowed memory address in memory mapping code during I/O processing at virtual SCSI might cause a guest OS on an ESXi host to mark guest file system as read-only. As a result, Kubernetes control plane nodes might go into Read-only mode. In the vmkernel logs, you see multiple error messages such as `failed to pin: I/O error.`

This issue is resolved in this release.

PR 3470731: Unsupported SCSI Read Mode Sense Page commands to a Raw Disk Mapping (RDM) target might cause virtual machines to become unresponsive

A large number of unsupported SCSI Read Mode Sense Page commands to a RDM target from a VM configured with an RDM device might exceed the storage heap and cause both the datastore and the VM to become unresponsive.

This issue is resolved in this release. The fix prevents blocking VM I/O operations by optimizing the handling of unsupported SCSI commands or mode pages. Specifically, in passthrough mode used for RDM devices, the system no longer attempts to process such unsupported commands in a way that consumes storage heap resources.

PR 3398467: vSphere Virtual Volumes daemon fails after converting a VASA provider from external to internal

Due to an issue with handling IDs during an unbind operation for some vSphere API for Storage Awareness (VASA) providers, in some tasks such as converting a VASA provider from external to internal, the vSphere Virtual Volumes daemon vvold might fail as it cannot map unique IDs.

This issue is resolved in this release. With the fix, vvold gracefully handles such conditions and stops the unbind operation with message in the logs instead of failing.

PR 3388843: You cannot activate Kernel DMA Protection on a virtual machine with Windows OS and Intel processor

When virtual Input-Output Memory Management Unit (vIOMMU) is active on a virtual machine with Windows OS and an Intel CPU, you might not be able to activate Kernel DMA Protection.

This issue is resolved in this release. The fix adds `acpi.dmar.enableDMAProtection=TRUE` to the vmx advanced settings that you can use if required.

PR 3469106: ESXi hosts intermittently disconnect from the Active Directory domain or from vCenter

Memory leaks might occur in Likewise during Active Directory operations or if smart card authentication is active on an ESXi host. As a result, Likewise processes might run out of memory and ESXi hosts intermittently disconnect from the Active Directory domain or from vCenter. In the `/var/log/vmkernel.log` file, you see messages similar to:

```
yyyy-mm-dd In(182) vmkernel: cpu72:2110465)uw.2110464 (44739) requires 1024 KB, asked 1024 KB from likewise (792) which has 93112 KB occupied and 72 KB available.
```

```
yyyy-mm-dd In(182) vmkernel: cpu72:2110465)Admission failure in path: host/vim/vmvisor/likewise:lwsmd.2110464:uw.2110464
```

In the `hostd-probe.log` file you see a message such as: `hostd detected to be non-responsive.`

This issue is resolved in this release. The fix adds a system service that monitors Likewise memory usage and restarts relevant services in case memory consumption approaches Likewise limits.

PR 3477734: ESXi host fails with a purple diagnostic screen while activating HClock

If for some reason an ESXi host fails to allocate memory for the activation of the HClock capability, the error handling goes into CPU wait state while it still holds a lock. As a result, the host fails with a purple diagnostic screen, and you see backtraces such as:

```
[0x2b8c]RCU_WaitForGracePeriod@vmkernel#nover stack:
[0xa000]vmk_HashRelease@vmkernel#nover+ stack:
```

```
[0xa0000]NetSchedHClkConnect@(netsched_hclk)#<None> stack:
```

This issue is resolved in this release.

PR 3489859: Migration of virtual machines fails with an error "Failed to allocate migration heap" on the source ESXi host

In very rare cases, if a virtual machine powers off before a running migration completes, ESXi might fail to clean up the migration heap. If the memory leak continues over time, the migration heap might be exhausted, and virtual machines cannot migrate from such ESXi hosts.

This issue is resolved in this release.

PR 3499302: If a virtual machine migrates to an ESXi host undergoing NSX update, the Distributed Firewall rule might be detached from that host

During NSX update or upgrade, ESXi hosts go into maintenance mode and the Distributed Resource Scheduler might trigger mass migration of VMs. As a result, vSphere vMotion with the Distributed Firewall rule might fail on some VMs and cause the DFW rule to be detached from the host.

This issue is resolved in this release.

PR 3477772: Encrypted virtual machines with active Change Block Tracking (CBT) might intermittently power off after a rekey operation

Due to a race condition between the VMX and hostd services for a specific VMcrypt-related reconfiguration, encrypted VMs with active CBT might unexpectedly power off during a rekey operation.

This issue is resolved in this release.

PR 3469639: Logging stops on all log files and configured remote host targets on ESXi hosts and hosts might become unresponsive

A rare deadlock situation in the ESXi log daemon vmsyslogd might cause logging to stop on all log files and configured remote host targets on ESXi hosts. As a result, the hosts might become unresponsive. The issue might occur as the result of multiple syslog reloads.

This issue is resolved in this release.

PR 3458045: ESXi hosts intermittently fail with purple diagnostic screen due to a rare race condition

A very rare race condition might lead to accessing an interface address while it is freed from another context. As a result, ESXi hosts might intermittently fail with purple diagnostic screen and an error such as `#PF Exception 14 in world 1001391810:dhclient-uw IP 0x420003562680`.

This issue is resolved in this release.

PR 3398458: ESXi hosts become unresponsive due to pointer blocks cached filling VMFS heap to its limit

Copies of pointer blocks that are part of data transactions between ESXi hosts might be cached in the VMFS heap even after the transactions are completed. Such cached pointer blocks might fill in the heap to its limit and as a result, ESXi hosts become unresponsive from vCenter and eventually virtual machines might go offline.

This issue is resolved in this release.

PR 3390998: ESXi hosts might fail with a purple diagnostic screen due to an incomplete cleanup of a SCSI path after deleting a controller

If a controller is deleted before a device claim process completes, the `namespace` object is removed, but the SCSI Path object remains. When adding a new `namespace`, the SCSI Path might prematurely become claimable, leading to a partially populated `PsaNvmePath` object. If a claim thread picks up that path before initialization, the ESXi host might fail with a purple diagnostic screen with an error such as:`@BlueScreen: #PF Exception 14 in world 1001448541:Cmpl-vmhba66 IP 0x420025354538 addr 0x0`.

This issue is resolved in this release.

PR 3358960: In the vmkernel logs, you see multiple errors from the network interface drivers for an unsupported feature

When the ESXi NetQueue load balancer, which uses load balancing algorithms to manage the vNIC and VMkernel adapter filters, sends a VMK_UPLINK_QUEUE_FEAT_LATENCY request to a nmlx5 driver, you see multiple errors in the vmkernel logs. VMK_UPLINK_QUEUE_FEAT_LATENCY is a software queue feature and if a client request contains this feature, the NIC drivers do not allocate queues but log errors that an unregistered feature is requested.

This issue is resolved in this release. The fix masks VMK_UPLINK_QUEUE_FEAT_LATENCY in requests for queue allocation from NIC drivers.

PR 3441399: You cannot upload virtual machine template of version ESXi 7.0 Update 3 with a DirectPath I/O device to the Content Library

When you create a template from an ESXi 7.0 Update 3 VM with a DirectPath I/O device, the upload to the Content Library fails with a `Null Pointer` exception. In the vSphere Client, you see an error such as `Failed to export OVF package. ThrowableProxy.cause A general runtime error occurred. An error occurred: java.lang.NullPointerException` . In the `cls.log` , you see the error `java.lang.NullPointerException: null` .

This issue is resolved in this release.

PR 3393549: Windows and Citrix virtual machines with vGPU intermittently fail with driver-related blue diagnostic screen

Windows and Citrix VMs with a vGPU device might intermittently run out of file handles and fail with a blue diagnostic screen.

This issue is resolved in this release. The fix allows you to increase the number of file handles to 16384 for Windows and Citrix VMs with a vGPU device. For more information, see KB 369633.

PR 3434172: You cannot apply a reverse path filter for virtual machines in promiscuous mode even though /Net/ReversePathFwdCheckPromisc is active

In very specific conditions, after an upgrade of a distributed virtual switch or uninstalling an NSX transport node on an ESXi host with converged distributed virtual switch that contains a port group with active promiscuous mode, you might see some networking issues, including:

1. You cannot apply a reverse path filter for virtual machines in promiscuous mode even though **/Net/ReversePathFwdCheckPromisc** is active.
2. Intermittent packet connectivity issues when using promiscuous mode on a distributed virtual switch with multiple uplinks.

This issue is resolved in this release.

PR 3420117: ESXi hosts become non-responding during a failover

In a failover task, ESXi sends the `INQUIRY page-83` command to the target host to get port parameters but in a ghost LUN configuration some target arrays might provide unformatted output for this command. As a result, the failover task fails and in the kernel logs you see the message `Target completed the Inquiry VPD Page 0x83 request with good status but returned junk data` .

This issue is resolved in this release.

PR 3437311: The intrusion detection and prevention system (IDS/IPS) might report false positives for dropped packets in vSphere reporting tools

In environments with active IDS/IPS, ESXi might report false positives for dropped packets to network monitoring solutions such as Aria Operations. If you deactivate IDS/IPS, the count of dropped packets falls. The issue affects all virtual machines connected to NSX segments.

This issue is resolved in this release.

PR 3398462: Virtual machines residing on a vSphere Virtual Volumes datastore might become inaccessible due to a size reporting issue

An issue in the VASA provider might report an inflated size for the home directory that contains metadata files for a virtual machine and VMFS automatically expands to accommodate the larger size. However, if the VASA provider later reports the correct size, VMFS cannot shrink, and the home directory cannot open. As a result, all VM files stored in the home folder become inaccessible and you cannot access the VMs.

This issue is resolved in this release.

PR 3407529: Virtual machines with snapshots and active encryption experience higher I/O latency

In rare cases, encrypted VMs with snapshots might experience higher than expected latency. This issue occurs due to unaligned I/O operations that generate excessive metadata requests to the underlying storage and lead to increased latency.

This issue is resolved in this release. To optimize performance, the VMcrypt I/O filter is enhanced to allocate memory in 4K-aligned blocks for both read and write operations. This reduction in metadata overhead significantly improves overall I/O performance.

PR 3410295: You see gaps in the collection of metrics for some virtual machines

Due to a time sync issue, collection of data for some VMs might fail and you do not see any performance data in platforms such as Aria Operations. In the */var/run/log/vobd.log* on the ESXi host, you see errors such as: `1149:2024-06-11T05:01:11.250Z: [ClockCorrelator] 7826272852729us: [vob.clock.correction.adjtime.sync] system clock synchronized to upstream time servers`

This issue is resolved in this release. The fix caches results from Stats Registry queries with selected dynamic counters to make sure metrics are consistent.

PR 3401554: vSAN Original Storage Architecture (OSA) virtual machines with large-sized VMDKs might experience performance degradation or become inaccessible

In vSAN OSA environments of version 8.0 and later, VMDK objects with a large amount of used capacity, such as close to the maximum of 62 TB, might overload the scrubber, which leads to a race condition that might cause such objects to experience performance degradation or become inaccessible.

This issue is resolved in this release.

PR 3359530: ESXi hosts fail with purple diagnostic screen due to a pNIC driver memory overload

In a rare situation when memory-intensive workloads that fragment system memory run in parallel with throughput-intensive workloads on a virtual switch configured with 9000 MTU or more, ESXi hosts might fail with a purple diagnostic screen. As a result, power-on virtual machines become temporarily unavailable. The issue occurs because memory allocation requests from the pNIC driver overload the memory subsystem with a growing networking packet heap, which causes ESXi to fail with a stack trace at `/var/cores/` such as:

```
NMI_Interrupt@vmkernel#nover+0x561
IDTNMIWork@vmkernel#nover+0x7f
Int2_NMI@vmkernel#nover+0x19
gate_entry@vmkernel#nover+0x68
Timer_GetCycles@vmkernel#nover+0x2
SP_WaitLockIRQ@vmkernel#nover+0xd5
SPLockIRQWork@vmkernel#nover+0x3e
Heap_AlignWithTimeoutAndRA@vmkernel#nover+0xea
Pkt_AllocHandleWithSize@vmkernel#nover+0x165
Pkt_AllocWithFlags@vmkernel#nover+0xd
vmk_PktAllocForDMAEngine@vmkernel#nover+0x46
```

This issue is resolved in this release. With the fix, you can reserve enough memory for the pNIC driver using the command `esxcli system settings kernel set -s netPktJumboSlabMinSize -v <MEMORY_SIZE_TO_RESERVE_IN_MB>`. To define the amount of memory you need to reserve, use this formula: `reservation size = (numPnics * numRxQueues * (rxRingSize + 64) + numPcpus *256) * 10KB`. For example, for an ESXi host with 72 PCPUs and 4 PNICs with 10 queues of ring size set to 4K each, the reservation is about 2048 MB.

PR 3400360: VMFS6 automatic UNMAP feature might fail to reclaim filesystem space beyond 250GB

In certain cases, when you delete a filesystem space of more than 250GB on a VMFS6 volume, for example 1 TB, if the volume has no active references such as active VMs, then the VMFS6 automatic UNMAP feature might fail to reclaim the filesystem space beyond 250GB.

This issue is resolved in this release.

PR 3355390: An ESXi host fails with a purple diagnostic screen and message @BlueScreen: NMI IPI: Panic requested by another PCPU

If firewall rules in your environment result in packets moving across multiple portsets, a race condition might cause software locks to end in a deadlock. As a result, an ESXi host might fail with a purple diagnostic screen and message `@BlueScreen: NMI IPI: Panic requested by another PCPU`.

This issue is resolved in this release.

PR 3404507: ESXi hosts might fail with purple diagnostic screen due to a rare memory allocation error

If a VM power-on fails, a function that allocates memory on the heap might not free certain allocations and cause a memory leak. As a result, the ESXi host fails with a purple diagnostic screen in `World_DestroyHeap` with `NOT_IMPLEMENTED bora/vmkernel/main/world.c:2293` and `Unable to complete wait for non-empty heap` errors.

This issue is resolved in this release. The fix makes sure a cleanup function runs to free allocations to prevent the issue.

PR 3406156: Extracting a vSphere Lifecycle Manager image from an existing ESXi host might fail after a kernel configuration change

Each update of the kernel configuration also triggers an update to the `/bootbank/useropts.gz` file, but due to a rare issue, the `basemisc.tgz` might not contain the default `useropts` file after such an update. As a result, when attempting to extract a vSphere Lifecycle Manager image from an existing ESXi host, the absence of the default `useropts` file leads to failure to create the `esx-base.vib` file and the operational also fails.

This issue is resolved in this release.

PR 3396464: A lost cleanup callback might cause purple diagnostic screen failures in vSAN clusters with Remote Direct Memory Access (RDMA)

In Express Storage Architecture (ESA) vSAN clusters with active RDMA, a rare issue with a lost cleanup callback might cause a purple diagnostic screen failure with a message such as `Failed to wait for object exit`. The issue is specific to RDMA use in vSAN.

This issue is resolved in this release.

PR 3398279: Creating a vSAN File Service fails when you use IPs within the 172.17.0.0/16 range as mount points

Prior to vSphere 7.0 Update 3v, you must change your network configuration in cases when the specified file service network overlaps with the Docker default internal network 172.17.0.0/16. As a result, in the network configuration step of the File Service activation workflow, when you enter a subnet with 172.17.**.**, you see a warning and you cannot create vSAN File Services.

This issue is resolved in this release. The fix routes traffic to the correct endpoint to avoid possible conflicts. The fix is in the vSAN File Service Virtual Machine, and if you upgrade the file service to 7.0 Update 3v, you can ignore the conflict warning and continue the file service activation with subnet 172.17.0.0/16.

PR 3365863: ESXi hosts might fail with a purple diagnostic screen during high volume of outstanding I/O requests combined with slow storage performance

Under heavy I/O loads, a bug in the ESXi storage stack can cause an ESXi host to fail with a purple diagnostics screen if the storage cannot process the I/O requests quickly and some virtual machines on the ESXi host start issuing I/O resets.

This issue is resolved in this release.

PR 3332717: An ESXi hosts might fail with a purple diagnostic screen during a file close on a NFS41 datastore

A file close on a NFS41 datastore might lead to memory corruption in a layer common across file systems. A subsequent file open on an NFSv3 datastore picks up the same memory zone. As a result, the ESXi host might fail with a purple diagnostic screen with a backtrace similar to:

```
NFSDestroySchedQueue NFS
Sched_DestroySchedQueue
NFSVolume_DestroySchedQHandle
```

This issue is resolved in this release.

PR 3352007: ESXi hosts might fail with a purple diagnostics screen and with errors for CpuSchedWait() and FS3_ReportCorruption() in the backtrace

In a data corruption scenario, the corruption report routine requires to load the VMFS datastore volume header metadata and perform a validation. In very rare cases, a spinlock might prevent reading this metadata and as a result, ESXi hosts might fail with a purple diagnostics screen. In the backtrace, you see errors for `CpuSchedWait()` and `FS3_ReportCorruption()`.

This issue is resolved in this release. The fix enhances the data corruption report routine to allow skipping the read on the volume header metadata for such rare cases.

PR 3367834: A fault tolerance secondary virtual machine might restart by accident

In very rare cases, a fault tolerance secondary VM might restart unexpectedly while other fault tolerance VMs power off or migrate from the ESXi host.

This issue is resolved in this release.

PR 3389767: During a vSphere vMotion migration of a fault tolerant Primary VM with encryption, the migration task might fail and vSphere FT failover occurs

In rare cases, the encryption key package might not be sent or received correctly during a vSphere vMotion migration of a fault tolerant Primary VM with encryption, and as a result the migration task fails and vSphere FT failover occurs.

This issue is resolved in this release. The fix sends the encryption key at the end of the vSphere FT checkpoint to avoid errors.

PR 3382561: Virtual machines that share the same encryption key are randomly locked after the ESXi host reboots

When cloned from a single VM, several VMs can share the same encryption key. After an ESXi host reboot, each key of such VMs is added to the key cache, but while the first key addition succeeds, subsequent additions fail because the key already exists in the cache, and the key is removed. As a result, such VMs become locked.

This issue is resolved in this release.

esx-update_7.0.3-0.145.24723872

Patch Category	Bugfix

PRs Fixed	3422040, 3412449, 3400844, 3365671
CVE numbers	N/A

Updates the `loadesx` and `esx-update` VIBs to resolve the following issue:

PR 3412449: Remediation of ESXi hosts might fail due to a timeout in the update of the VMware-VM-Tools component

While upgrading ESXi hosts by using vSphere Lifecycle Manager, remediation of the VMware-VM-Tools component might occasionally fail due to a timeout. The issue occurs when the update process takes longer than the timeout setting of 30 sec for the VMware-VM-Tools component.

This issue is resolved in this release. The fix increases the timeout limit to 120 sec.

Broadcom-ntg3_4.1.15.0-4vmw.703.0.145.24723872

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMW_bootbank_ntg3_4.1.15.0-4vmw.703.0.145.24723872
PRs Fixed	3411044
CVE numbers	N/A

Updates the `ntg3` VIB to resolve the following issue:

PR 3411044: ESXi host might lose network connectivity due to a very rare issue with the ntg3 driver

A data race in the handling of tx queue full situation in the ntg3 driver might cause in very rare cases the TX queue to stop transmitting packets. As a result, you see either virtual machines or ESXi host management network, or both, lose connectivity. In the vmkernel log of the affected ESXi host, you see messages such as `Uplink: XXXX: Queue 0 of device vmnicX stuck, resetting the device` and/or `Vmxnet3: XXXXX: XXXX, portID(XXXXX): Hang detected.`

This issue is resolved in this release. The fix is part of ntg3 4.1.15.

VMware-NVMeoF-TCP_1.0.0.7-1vmw.703.0.145.24723872

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A

Affected Software	N/A
Affected VIBs	• VMW_bootbank_nvmetcp_1.0.0.7-1vmw.703.0.145.24723872
PRs Fixed	3437679, 3414590, 3364569
CVE numbers	N/A

Updates the `nvmetcp` VIB to resolve the following issues:

PR 3414590: Snapshot tasks on virtual machines on NVMe/TCP datastores might take much longer than on VMs provisioned on NVMe/FC datastores

When creating or deleting a snapshot on a VM provisioned on datastores backed by NVMe/TCP namespaces, such tasks might take much longer than on VMs provisioned on datastores backed by NVMe/FC namespaces. The issue occurs because the nvmetcp driver handles some specific NVMe commands not in the way the NVMe/TCP target systems expect.

This issue is resolved in this release.

PR 3437679: ESXi host fails with a purple diagnostic screen due to mishandling a canceled NVMe write command

In rare cases, a large-size NVMe write command might be canceled due to an I/O timeout but the nvmetcp driver might again complete the command and this causes the ESXi host to fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3364569: If a NVMe/TCP driver fails to process an I/O command, an ESXi host might disconnect from a storage array

If your ESXi hosts connect to storage arrays and perform read/write operations by using NVMe/TCP connections, when a NVMe/TCP driver fails to process an I/O command, ESXi might cancel the process with an abort command. As a result, an ESXi host might disconnect from a storage array and end previous I/O queues.

This issue is resolved in this release.

ESXi_7.0.3-0.140.24723868

PR 3408358: Security scans on ESXi hosts with OpenSSH 8.8 show multiple CVEs

When for some reason you need to activate OpenSSH on an ESXi host, if the OpenSSH version is 8.8 and you run a security scan, you might see multiple CVEs.

This issue is resolved in this release. The fix updates OpenSSH to version 9.3p2 and backports security fixes from later versions: CVE-2024-6387, CVE-2023-51385, CVE-2023-51384, CVE-2023-48795, CVE-2023-38408. The version string is updated to **OpenSSH_9.3p2 vmw9.8p1** to indicate the backported patches.

esx-update_7.0.3-0.140.24723868

Patch Category	Security
Patch Severity	Critical

PRs Fixed	N/A
CVE numbers	N/A

This patch updates the `esx-update` and `loadesx` VIBs.

VMware-VM-Tools_12.5.1.24649672-24723868

Patch Category	Security
Patch Severity	Critical
Host Reboot Required	No
Virtual Machine Migration or Shutdown Required	No
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs Included	• VMware_locker_tools-light_12.5.1.24649672-24723868
PRs Fixed	3494213, 3409318
CVE numbers	N/A

This patch updates the `tools-light` VIB:

The following VMware Tools ISO images are bundled with ESXi 7.0 Update 3v:

- **windows.iso**: VMware Tools 12.5.1 supports the following 64-bit Windows versions:- Windows 7 SP1 or Windows Server 2008 R2 SP1 and later.
  For **windows.iso** support for 32-bit Windows versions: Windows 7 SP1 or Windows Server 2008 R2 SP1 and later, refer to VMware Tools 12.4.5 Release Notes.
  VMware Tools 12.5.0 provides support for Windows Server 2025, but make sure your system supports Windows 2025 if you plan to use Windows 2025 as a guest OS on virtual machines. For more information, see Installing Windows Server 2025 on a VMware Virtual Machine.
- **linux.iso**: VMware Tools 10.3.25 ISO image for Linux OS with **glibc** 2.11 or later.

The following VMware Tools ISO images are available for download:

- VMware Tools 11.0.6:
  – **windows.iso**: for Windows Vista (SP2) and Windows Server 2008 Service Pack 2 (SP2).

- VMware Tools 10.0.12:
  - **winPreVista.iso**: for Windows 2000, Windows XP, and Windows 2003.
  - **linuxPreGLibc25.iso**: supports Linux guest operating systems earlier than Red Hat Enterprise Linux (RHEL) 5, SUSE Linux Enterprise Server (SLES) 11, Ubuntu 7.04, and other distributions with **glibc** version earlier than 2.5.
- **solaris.iso**: VMware Tools image 10.3.10 for Solaris.
- **darwin.iso**: Supports Mac OS X versions 10.11 and later. VMware Tools 12.1.0 was the last regular release for macOS. For more details, see VMware knowledge base article 88698.

Follow the procedures listed in the following documents to download VMware Tools for platforms not bundled with ESXi:

- Updating VMware Tools
- VMware Tools for hosts provisioned with Auto Deploy
- What Every vSphere Admin Must Know About VMware Tools
- Earlier versions of VMware Tools
- VMware Tools 12.5.1 Release Notes

Related CVE numbers	CVE-2025-41226, CVE-2025-41227, CVE-2025-41228

This patch updates the following issues:

PR 3425364: Setting `cloud-init guestInfo` variables by regular users in the guest results into an error

Starting with ESXi 7.0 Update 3v, setting `cloud-init guestInfo` variables by regular users in the guest results into an error due to design changes.

This issue is resolved in this release. For more information, see KB 377267.

PR 3406033: ESXi host fails with a purple diagnostic screen due to a rare physical CPU (PCPU) lockup

In the vSphere Client, when you use the **Delete from Disk** option to remove a virtual machine from a vCenter system and delete all VM files from the datastore, including the configuration file and virtual disk files, if any of the files is corrupted, a rare issue with handling corrupted files in the delete path might lead to a PCPU lockup. As a result, the ESXi host fails with a purple diagnostic screen and a message such as `NMI IPI: Panic requested by another PCPU.`

This issue is resolved in this release.

PR 3484786: ESXi installation on an iSCSI LUN fails as the ESXi iSCSI Boot Firmware Table (iBFT) module fails to discover the LUN

In some cases, the iBFT control structure might have an optional expansion for which the ESXi vmkibft module doesn't have a proper check. As a result, iSCSI LUN discovery by using iBFT might fail and cause failure of the ESXi installation on the iSCSI LUN.

This issue is resolved in this release.

PR 3423217: You see vendor name of some Solidigm NVMe devices as Unknown

In the ESXi Host Client, under **Manage > Hardware > PCI Devices**, and in the vSphere Client, under **Host > Configure > Hardware > PCI Devices > All PCI Devices**, you might see the vendor name of some Solidigm NVMe devices as `Unknown`.

This issue is resolved in this release.

PR 3398537: ESXi host fails with a purple diagnostic screen due to an I/O race with an error PSOD @BlueScreen: ASSERT bora/lib/misc/bitvector.c:632

Due to a rare I/O race condition on virtual machines backed by a vSphere Virtual Volume, the ESXi host might fail with a purple diagnostic screen and an error such as `PSOD @BlueScreen: ASSERT bora/lib/misc/bitvector.c:632`.

This issue is resolved in this release.

PR 3371201: The hostd service might generate core dumps during upgrade from ESXi 6.7 to 7.x when SNMP traps are configured

In very rare cases, a missing SNMP port value when SNMP traps are configured during an upgrade from ESXi 6.7 to 7.x, might lead to hostd core dumps.

This issue is resolved in this release.

PR 3352051: Syslog configuration changes in a host profile that you use to provision ESXi host with Auto Deploy stateful install do not persist across reboots

If you change the syslog configuration of a host profile and provision ESXi hosts with that profile by using the Auto Deploy stateful install, changes might not persist after the hosts reboot.

This issue is resolved in this release.

PR 3396010: Controller VMs with direct I/O devices in third-party hyper converged infrastructure environments experience guest kernel soft lockups

A rare race condition between the interrupt virtualization and the VMkernel CPU scheduler in an ESXi host might result in guest kernel soft lockups on controller VMs with direct I/O devices in third-party hyper converged infrastructure environments. The soft locks cause virtual machines in the entire cluster to lose NFS storage connectivity and I/O access.

This issue is resolved in this release.

PR 3359386: If the Latency Sensitivity parameter of a virtual machine is set to High, you cannot add memory to that VM when powered off

If you use the vSphere Client to set the `Latency Sensitivity` parameter of a VM to `High` , attempts to add memory to such a VM when powered off might fail with an error such as `A specified parameter was not correct: spec.memoryAllocation` .

This issue is resolved in this release.

PR 3403867: Setting the CPU limit to 0 makes virtual machines unresponsive

If for any reason you set the CPU limit of running virtual machines to `0` , this causes CPU starvation and the VMs become unresponsive.

This issue is resolved in this release.

PR 3457552: You might see multiple hardware sensor alerts due to a Baseboard Management Controller (BMC) issue

An underlying BMC issue might cause ESXi hardware health monitoring to produce multiple alerts for hardware sensors on ESXi hosts, which you see in the vSphere Client under **Monitor > Tasks and Events**.

This issue is resolved in this release. The fix logs raw sensor data directly from IPMI to provide a data point to debug possible BMC issues that cause false alerts but cannot prevent BMC issues from occuring.

PR 3484794: Restoring the iSCSI configurations on an ESXi host might fail during boot due to stale entries in the ConfigStore database

If the ConfigStore database on an ESXi host has stale iSCSI configurations related to hardware iSCSI adapters, the iSCSI jumpstart might fail and restoring the iSCSI configuration on that host also fails during boot.

This issue is resolved in this release.

PR 3484793: Discovery of iSCSI dynamic targets, LUNs, and datastores fails on ESXi host reboot

In some cases, dynamic discovery of targets in systems that use dynamic discovery addresses for iSCSI configuration might fail. As a result, you do not see iSCSI targets, LUNs, and datastores after a reboot of ESXi hosts. The dynamic discovery of iSCSI targets might also fail when the Challenge-Handshake Authentication Protocol (CHAP) is active on the ESXi host.

This issue is resolved in this release.

PR 3458283: A rare Baseboard Management Controller (BMC) issue might cause some applications to become unresponsive

If an application sends an IPMI request to the BMC while it resets, such requests remain indefinitely pending and cause the applications to become unresponsive.

This issue is resolved in this release. The fix updates the IPMI driver to handle such conditions.

PR 3485174: Guest OS might mark file system read-only after repeated I/O failure which can cause Kubernetes control plane nodes to go into Read-only mode

An issue with the check for max allowed memory address in memory mapping code during I/O processing at virtual SCSI might cause a guest OS on an ESXi host to mark guest file system as read-only. As a result, Kubernetes control plane nodes might go into Read-only mode. In the vmkernel logs, you see multiple error messages such as `failed to pin: I/O error.`

This issue is resolved in this release.

PR 3470731: Unsupported SCSI Read Mode Sense Page commands to a Raw Disk Mapping (RDM) target might cause virtual machines to become unresponsive

A large number of unsupported SCSI Read Mode Sense Page commands to a RDM target from a VM configured with an RDM device might exceed the storage heap and cause both the datastore and the VM to become unresponsive.

This issue is resolved in this release. The fix prevents blocking VM I/O operations by optimizing the handling of unsupported SCSI commands or mode pages. Specifically, in passthrough mode used for RDM devices, the system no longer attempts to process such unsupported commands in a way that consumes storage heap resources.

PR 3398467: vSphere Virtual Volumes daemon fails after converting a VASA provider from external to internal

Due to an issue with handling IDs during an unbind operation for some vSphere API for Storage Awareness (VASA) providers, in some tasks such as converting a VASA provider from external to internal, the vSphere Virtual Volumes daemon vvold might fail as it cannot map unique IDs.

This issue is resolved in this release. With the fix, vvold gracefully handles such conditions and stops the unbind operation with message in the logs instead of failing.

PR 3414590: Snapshot tasks on virtual machines on NVMe/TCP datastores might take much longer than on VMs provisioned on NVMe/FC datastores

When creating or deleting a snapshot on a VM provisioned on datastores backed by NVMe/TCP namespaces, such tasks might take much longer than on VMs provisioned on datastores backed by NVMe/FC namespaces. The issue occurs because the nvmetcp driver handles some specific NVMe commands not in the way the NVMe/TCP target systems expect.

This issue is resolved in this release.

PR 3388843: You cannot activate Kernel DMA Protection on a virtual machine with Windows OS and Intel processor

When virtual Input-Output Memory Management Unit (vIOMMU) is active on a virtual machine with Windows OS and an Intel CPU, you might not be able to activate Kernel DMA Protection.

This issue is resolved in this release. The fix adds `acpi.dmar.enableDMAProtection=TRUE` to the vmx advanced settings that you can use if required.

PR 3469106: ESXi hosts intermittently disconnect from the Active Directory domain or from vCenter

Memory leaks might occur in Likewise during Active Directory operations or if smart card authentication is active on an ESXi host. As a result, Likewise processes might run out of memory and ESXi hosts intermittently disconnect from the Active Directory domain or from vCenter. In the `/var/log/vmkernel.log` file, you see messages similar to:

```
yyyy-mm-dd In(182) vmkernel: cpu72:2110465)uw.2110464 (44739) requires 1024 KB, asked 1024 KB from likewise (792) which has 93112 KB occupied and 72 KB available.
```

```
yyyy-mm-dd In(182) vmkernel: cpu72:2110465)Admission failure in path: host/vim/vmvisor/likewise:lwsmd.2110464:uw.2110464
```

In the `hostd-probe.log` file you see a message such as: `hostd detected to be non-responsive.`

This issue is resolved in this release. The fix adds a system service that monitors Likewise memory usage and restarts relevant services in case memory consumption approaches Likewise limits.

PR 3477734: ESXi host fails with a purple diagnostic screen while activating HClock

If for some reason an ESXi host fails to allocate memory for the activation of the HClock capability, the error handling goes into CPU wait state while it still holds a lock. As a result, the host fails with a purple diagnostic screen, and you see backtraces such as:

```
[0x2b8c]RCU_WaitForGracePeriod@vmkernel#nover stack:
[0xa000]vmk_HashRelease@vmkernel#nover+ stack:
[0xa0000]NetSchedHClkConnect@(netsched_hclk)#<None> stack:
```

This issue is resolved in this release.

PR 3489859: Migration of virtual machines fails with an error "Failed to allocate migration heap" on the source ESXi host

In very rare cases, if a virtual machine powers off before a running migration completes, ESXi might fail to clean up the migration heap. If the memory leak continues over time, the migration heap might be exhausted, and virtual machines cannot migrate from such ESXi hosts.

This issue is resolved in this release.

PR 3499302: If a virtual machine migrates to an ESXi host undergoing NSX update, the Distributed Firewall rule might be detached from that host

During NSX update or upgrade, ESXi hosts go into maintenance mode and the Distributed Resource Scheduler might trigger mass migration of VMs. As a result, vSphere vMotion with the Distributed Firewall rule might fail on some VMs and cause the DFW rule to be detached from the host.

This issue is resolved in this release.

PR 3477772: Encrypted virtual machines with active Change Block Tracking (CBT) might intermittently power off after a rekey operation

Due to a race condition between the VMX and hostd services for a specific VMcrypt-related reconfiguration, encrypted VMs with active CBT might unexpectedly power off during a rekey operation.

This issue is resolved in this release.

PR 3469639: Logging stops on all log files and configured remote host targets on ESXi hosts and hosts might become unresponsive

A rare deadlock situation in the ESXi log daemon vmsyslogd might cause logging to stop on all log files and configured remote host targets on ESXi hosts. As a result, the hosts might become unresponsive. The issue might occur as the result of multiple syslog reloads.

This issue is resolved in this release.

PR 3458045: ESXi hosts intermittently fail with purple diagnostic screen due to a rare race condition

A very rare race condition might lead to accessing an interface address while it is freed from another context. As a result, ESXi hosts might intermittently fail with purple diagnostic screen and an error such as `#PF Exception 14 in world 1001391810:dhclient-uw IP 0x420003562680`.

This issue is resolved in this release.

PR 3398458: ESXi hosts become unresponsive due to pointer blocks cached filling VMFS heap to its limit

Copies of pointer blocks that are part of data transactions between ESXi hosts might be cached in the VMFS heap even after the transactions are completed. Such cached pointer blocks might fill in the heap to its limit and as a result, ESXi hosts become unresponsive from vCenter and eventually virtual machines might go offline.

This issue is resolved in this release.

PR 3390998: ESXi hosts might fail with a purple diagnostic screen due to an incomplete cleanup of a SCSI path after deleting a controller

If a controller is deleted before a device claim process completes, the `namespace` object is removed, but the SCSI Path object remains. When adding a new `namespace` , the SCSI Path might prematurely become claimable, leading to a partially populated `PsaNvmePath` object. If a claim thread picks up that path before initialization, the ESXi host might fail with a purple diagnostic screen with an error such as:`@BlueScreen: #PF Exception 14 in world 1001448541:Cmpl-vmhba66 IP 0x420025354538 addr 0x0` .

This issue is resolved in this release.

PR 3358960: In the vmkernel logs, you see multiple errors from the network interface drivers for an unsupported feature

When the ESXi NetQueue load balancer, which uses load balancing algorithms to manage the vNIC and VMkernel adapter filters, sends a VMK_UPLINK_QUEUE_FEAT_LATENCY request to a nmlx5 driver, you see multiple errors in the vmkernel logs. VMK_UPLINK_QUEUE_FEAT_LATENCY is a software queue feature and if a client request contains this feature, the NIC drivers do not allocate queues but log errors that an unregistered feature is requested.

This issue is resolved in this release. The fix masks VMK_UPLINK_QUEUE_FEAT_LATENCY in requests for queue allocation from NIC drivers.

PR 3441399: You cannot upload virtual machine template of version ESXi 7.0 Update 3 with a DirectPath I/O device to the Content Library

When you create a template from an ESXi 7.0 Update 3 VM with a DirectPath I/O device, the upload to the Content Library fails with a `Null Pointer` exception. In the vSphere Client, you see an error such as `Failed to export OVF package. ThrowableProxy.cause A general runtime error occurred. An error occurred: java.lang.NullPointerException` . In the `cls.log` , you see the error `java.lang.NullPointerException: null` .

This issue is resolved in this release.

PR 3437679: ESXi host fails with a purple diagnostic screen due to mishandling a canceled NVMe write command

In rare cases, a large-size NVMe write command might be canceled due to an I/O timeout but the nvmetcp driver might again complete the command and this causes the ESXi host to fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3393549: Windows and Citrix virtual machines with vGPU intermittently fail with driver-related blue diagnostic screen

Windows and Citrix VMs with a vGPU device might intermittently run out of file handles and fail with a blue diagnostic screen.

This issue is resolved in this release. The fix allows you to increase the number of file handles to 16384 for Windows and Citrix VMs with a vGPU device. For more information, see KB 369633.

PR 3434172: You cannot apply a reverse path filter for virtual machines in promiscuous mode even though /Net/ ReversePathFwdCheckPromisc is active

In very specific conditions, after an upgrade of a distributed virtual switch or uninstalling an NSX transport node on an ESXi host with converged distributed virtual switch that contains a port group with active promiscuous mode, you might see some networking issues, including:

1. You cannot apply a reverse path filter for virtual machines in promiscuous mode even though **/Net/ ReversePathFwdCheckPromisc** is active.
2. Intermittent packet connectivity issues when using promiscuous mode on a distributed virtual switch with multiple uplinks.

This issue is resolved in this release.

PR 3420117: ESXi hosts become non-responding during a failover

In a failover task, ESXi sends the `INQUIRY page-83` command to the target host to get port parameters but in a ghost LUN configuration some target arrays might provide unformatted output for this command. As a result, the failover task fails and in the kernel logs you see the message `Target completed the Inquiry VPD Page 0x83 request with good status but returned junk data.`

This issue is resolved in this release.

PR 3437311: The intrusion detection and prevention system (IDS/IPS) might report false positives for dropped packets in vSphere reporting tools

In environments with active IDS/IPS, ESXi might report false positives for dropped packets to network monitoring solutions such as Aria Operations. If you deactivate IDS/IPS, the count of dropped packets falls. The issue affects all virtual machines connected to NSX segments.

This issue is resolved in this release.

PR 3398462: Virtual machines residing on a vSphere Virtual Volumes datastore might become inaccessible due to a size reporting issue

An issue in the VASA provider might report an inflated size for the home directory that contains metadata files for a virtual machine and VMFS automatically expands to accommodate the larger size. However, if the VASA provider later reports the correct size, VMFS cannot shrink, and the home directory cannot open. As a result, all VM files stored in the home folder become inaccessible and you cannot access the VMs.

This issue is resolved in this release.

PR 3411044: ESXi host might lose network connectivity due to a very rare issue with the ntg3 driver

A data race in the handling of tx queue full situation in the ntg3 driver might cause in very rare cases the TX queue to stop transmitting packets. As a result, you see either virtual machines or ESXi host management network, or both, lose connectivity. In the vmkernel log of the affected ESXi host, you see messages such as `Uplink: XXXX: Queue 0 of device vmnicX stuck, resetting the device` and/or `Vmxnet3: XXXXX: XXXX, portID(XXXXX): Hang detected.`

This issue is resolved in this release. The fix is part of ntg3 4.1.15.

PR 3407529: Virtual machines with snapshots and active encryption experience higher I/O latency

In rare cases, encrypted VMs with snapshots might experience higher than expected latency. This issue occurs due to unaligned I/O operations that generate excessive metadata requests to the underlying storage and lead to increased latency.

This issue is resolved in this release. To optimize performance, the VMcrypt I/O filter is enhanced to allocate memory in 4K-aligned blocks for both read and write operations. This reduction in metadata overhead significantly improves overall I/O performance.

PR 3410295: You see gaps in the collection of metrics for some virtual machines

Due to a time sync issue, collection of data for some VMs might fail and you do not see any performance data in platforms such as Aria Operations. In the */var/run/log/vobd.log* on the ESXi host, you see errors such as: `1149:2024-06-11T05:01:11.250Z: [ClockCorrelator] 7826272852729us: [vob.clock.correction.adjtime.sync] system clock synchronized to upstream time servers`

This issue is resolved in this release. The fix caches results from Stats Registry queries with selected dynamic counters to make sure metrics are consistent.

PR 3401554: vSAN Original Storage Architecture (OSA) virtual machines with large-sized VMDKs might experience performance degradation or become inaccessible

In vSAN OSA environments of version 8.0 and later, VMDK objects with a large amount of used capacity, such as close to the maximum of 62 TB, might overload the scrubber, which leads to a race condition that might cause such objects to experience performance degradation or become inaccessible.

This issue is resolved in this release.

PR 3359530: ESXi hosts fail with purple diagnostic screen due to a pNIC driver memory overload

In a rare situation when memory-intensive workloads that fragment system memory run in parallel with throughput-intensive workloads on a virtual switch configured with 9000 MTU or more, ESXi hosts might fail with a purple diagnostic screen. As a result, power-on virtual machines become temporarily unavailable. The issue occurs because memory allocation requests from the pNIC driver overload the memory subsystem with a growing networking packet heap, which causes ESXi to fail with a stack trace at `/var/cores/` such as:

```
NMI_Interrupt@vmkernel#nover+0x561
IDTNMIWork@vmkernel#nover+0x7f
Int2_NMI@vmkernel#nover+0x19
gate_entry@vmkernel#nover+0x68
Timer_GetCycles@vmkernel#nover+0x2
SP_WaitLockIRQ@vmkernel#nover+0xd5
SPLockIRQWork@vmkernel#nover+0x3e
Heap_AlignWithTimeoutAndRA@vmkernel#nover+0xea
Pkt_AllocHandleWithSize@vmkernel#nover+0x165
Pkt_AllocWithFlags@vmkernel#nover+0xd
vmk_PktAllocForDMAEngine@vmkernel#nover+0x46
```

This issue is resolved in this release. With the fix, you can reserve enough memory for the pNIC driver using the command `esxcli system settings kernel set -s netPktJumboSlabMinSize -v <MEMORY_SIZE_TO_RESERVE_IN_MB>`. To define the amount of memory you need to reserve, use this formula: `reservation size = (numPnics * numRxQueues * (rxRingSize + 64) + numPcpus *256) * 10KB`. For example, for an ESXi host with 72 PCPUs and 4 PNICs with 10 queues of ring size set to 4K each, the reservation is about 2048 MB.

PR 3412449: Remediation of ESXi hosts might fail due to a timeout in the update of the VMware-VM-Tools component

While upgrading ESXi hosts by using vSphere Lifecycle Manager, remediation of the VMware-VM-Tools component might occasionally fail due to a timeout. The issue occurs when the update process takes longer than the timeout setting of 30 sec for the VMware-VM-Tools component.

This issue is resolved in this release. The fix increases the timeout limit to 120 sec.

PR 3400360: VMFS6 automatic UNMAP feature might fail to reclaim filesystem space beyond 250GB

In certain cases, when you delete a filesystem space of more than 250GB on a VMFS6 volume, for example 1 TB, if the volume has no active references such as active VMs, then the VMFS6 automatic UNMAP feature might fail to reclaim the filesystem space beyond 250GB.

This issue is resolved in this release.

PR 3355390: An ESXi host fails with a purple diagnostic screen and message @BlueScreen: NMI IPI: Panic requested by another PCPU

If firewall rules in your environment result in packets moving across multiple portsets, a race condition might cause software locks to end in a deadlock. As a result, an ESXi host might fail with a purple diagnostic screen and message `@BlueScreen: NMI IPI: Panic requested by another PCPU`.

This issue is resolved in this release.

PR 3404507: ESXi hosts might fail with purple diagnostic screen due to a rare memory allocation error

If a VM power-on fails, a function that allocates memory on the heap might not free certain allocations and cause a memory leak. As a result, the ESXi host fails with a purple diagnostic screen in `World_DestroyHeap` with `NOT_IMPLEMENTED bora/vmkernel/main/world.c:2293` and `Unable to complete wait for non-empty heap` errors.

This issue is resolved in this release. The fix makes sure a cleanup function runs to free allocations to prevent the issue.

PR 3406156: Extracting a vSphere Lifecycle Manager image from an existing ESXi host might fail after a kernel configuration change

Each update of the kernel configuration also triggers an update to the `/bootbank/useropts.gz` file, but due to a rare issue, the `basemisc.tgz` might not contain the default `useropts` file after such an update. As a result, when attempting to extract a vSphere Lifecycle Manager image from an existing ESXi host, the absence of the default `useropts` file leads to failure to create the `esx-base.vib` file and the operational also fails.

This issue is resolved in this release.

PR 3396464: A lost cleanup callback might cause purple diagnostic screen failures in vSAN clusters with Remote Direct Memory Access (RDMA)

In Express Storage Architecture (ESA) vSAN clusters with active RDMA, a rare issue with a lost cleanup callback might cause a purple diagnostic screen failure with a message such as `Failed to wait for object exit`. The issue is specific to RDMA use in vSAN.

This issue is resolved in this release.

PR 3398279: Creating a vSAN File Service fails when you use IPs within the 172.17.0.0/16 range as mount points

Prior to vSphere 7.0 Update 3v, you must change your network configuration in cases when the specified file service network overlaps with the Docker default internal network 172.17.0.0/16. As a result, in the network configuration step of the File Service activation workflow, when you enter a subnet with 172.17.**.**, you see a warning and you cannot create vSAN File Services.

This issue is resolved in this release. The fix routes traffic to the correct endpoint to avoid possible conflicts. The fix is in the vSAN File Service Virtual Machine, and if you upgrade the file service to 7.0 Update 3v, you can ignore the conflict warning and continue the file service activation with subnet 172.17.0.0/16.

PR 3365863: ESXi hosts might fail with a purple diagnostic screen during high volume of outstanding I/O requests combined with slow storage performance

Under heavy I/O loads, a bug in the ESXi storage stack can cause an ESXi host to fail with a purple diagnostics screen if the storage cannot process the I/O requests quickly and some virtual machines on the ESXi host start issuing I/O resets.

This issue is resolved in this release.

PR 3364569: If a NVMe/TCP driver fails to process an I/O command, an ESXi host might disconnect from a storage array

If your ESXi hosts connect to storage arrays and perform read/write operations by using NVMe/TCP connections, when a NVMe/TCP driver fails to process an I/O command, ESXi might cancel the process with an abort command. As a result, an ESXi host might disconnect from a storage array and end previous I/O queues.

This issue is resolved in this release.

PR 3332717: An ESXi hosts might fail with a purple diagnostic screen during a file close on a NFS41 datastore

A file close on a NFS41 datastore might lead to memory corruption in a layer common across file systems. A subsequent file open on an NFSv3 datastore picks up the same memory zone. As a result, the ESXi host might fail with a purple diagnostic screen with a backtrace similar to:

```
NFSDestroySchedQueue NFS
Sched_DestroySchedQueue
```

`NFSVolume_DestroySchedQHandle`

This issue is resolved in this release.

PR 3352007: ESXi hosts might fail with a purple diagnostics screen and with errors for CpuSchedWait() and FS3_ReportCorruption() in the backtrace

In a data corruption scenario, the corruption report routine requires to load the VMFS datastore volume header metadata and perform a validation. In very rare cases, a spinlock might prevent reading this metadata and as a result, ESXi hosts might fail with a purple diagnostics screen. In the backtrace, you see errors for `CpuSchedWait()` and `FS3_ReportCorruption()`.

This issue is resolved in this release. The fix enhances the data corruption report routine to allow skipping the read on the volume header metadata for such rare cases.

PR 3367834: A fault tolerance secondary virtual machine might restart by accident

In very rare cases, a fault tolerance secondary VM might restart unexpectedly while other fault tolerance VMs power off or migrate from the ESXi host.

This issue is resolved in this release.

PR 3389767: During a vSphere vMotion migration of a fault tolerant Primary VM with encryption, the migration task might fail and vSphere FT failover occurs

In rare cases, the encryption key package might not be sent or received correctly during a vSphere vMotion migration of a fault tolerant Primary VM with encryption, and as a result the migration task fails and vSphere FT failover occurs.

This issue is resolved in this release. The fix sends the encryption key at the end of the vSphere FT checkpoint to avoid errors.

PR 3382561: Virtual machines that share the same encryption key are randomly locked after the ESXi host reboots

When cloned from a single VM, several VMs can share the same encryption key. After an ESXi host reboot, each key of such VMs is added to the key cache, but while the first key addition succeeds, subsequent additions fail because the key already exists in the cache, and the key is removed. As a result, such VMs become locked.

This issue is resolved in this release.

ESXi-7.0U3v-24723872-no-tools

Profile Name	ESXi-7.0U3v-24723872-no-tools
Build	For build information, see the Patches Contained in This Release section.
Vendor	Broadcom, Inc.
Release Date	May 20, 2025
Acceptance Level	PartnerSupported
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_bootbank_native-misc-drivers_7.0.3-0.145.24723872 • VMware_bootbank_vsan_7.0.3-0.145.24723872 • VMware_bootbank_bmcal_7.0.3-0.145.24723872 • VMware_bootbank_esx-xserver_7.0.3-0.145.24723872 • VMware_bootbank_gc_7.0.3-0.145.24723872 • VMware_bootbank_esx-base_7.0.3-0.145.24723872 • VMware_bootbank_esxio-combiner_7.0.3-0.145.24723872

	• VMware_bootbank_trx_7.0.3-0.145.24723872 • VMware_bootbank_cpu-microcode_7.0.3-0.145.24723872 • VMware_bootbank_esx-dvfilter-generic-fastpath_7.0.3-0.145.24723872 • VMware_bootbank_vsanhealth_7.0.3-0.145.24723872 • VMware_bootbank_crx_7.0.3-0.145.24723872 • VMware_bootbank_vdfs_7.0.3-0.145.24723872 • VMware_bootbank_loadesx_7.0.3-0.145.24723872 • VMware_bootbank_esx-update_7.0.3-0.145.24723872 • VMW_bootbank_ntg3_4.1.15.0-4vmw.703.0.145.24723872 • VMW_bootbank_nvmetcp_1.0.0.7-1vmw.703.0.145.24723872
PRs Fixed	3406035, 3477734, 3489859, 3352051, 3457552, 3485174, 3469639, 3470731, 3485586, 3484794, 3484793, 3484786, 3477773, 3469106, 3477257, 3476746, 3475049, 3454755, 3469189, 3466996, 3458045, 3435833, 3447991, 3443815, 3432572, 3432690, 3441101, 3404668, 3434172, 3437311, 3371201, 3367834, 3398462, 3410295, 3390998, 3398458, 3388843, 3398467, 3430801, 3408807, 3420117, 3417327, 3423849, 3417227, 3417328, 3404126, 3408129, 3408008, 3408126, 3398534, 3400360, 3406033, 3398361, 3398279, 3407212, 3411695, 3396010, 3412537, 3352007, 3404202, 3402976, 3396464, 3407529, 3408143, 3336865, 3403867, 3389767, 3366075, 3365863, 3404507, 3403906, 3405760, 3401554, 3398537, 3355390, 3359530, 3393549, 3367426, 3359386, 3382561, 3358960, 3422040, 3412449, 3400844, 3365671, 3411044, 3437679, 3414590, 3364569
Related CVE numbers	CVE-2025-41226, CVE-2025-41227, CVE-2025-41228

This patch updates the following issues:

PR 3425364: Setting `cloud-init guestInfo` variables by regular users in the guest results into an error

Starting with ESXi 7.0 Update 3v, setting `cloud-init guestInfo` variables by regular users in the guest results into an error due to design changes.

This issue is resolved in this release. For more information, see KB 377267.

PR 3406033: ESXi host fails with a purple diagnostic screen due to a rare physical CPU (PCPU) lockup

In the vSphere Client, when you use the **Delete from Disk** option to remove a virtual machine from a vCenter system and delete all VM files from the datastore, including the configuration file and virtual disk files, if any of the files is corrupted, a rare issue with handling corrupted files in the delete path might lead to a PCPU lockup. As a result, the ESXi host fails with a purple diagnostic screen and a message such as `NMI IPI: Panic requested by another PCPU.`

This issue is resolved in this release.

PR 3484786: ESXi installation on an iSCSI LUN fails as the ESXi iSCSI Boot Firmware Table (iBFT) module fails to discover the LUN

In some cases, the iBFT control structure might have an optional expansion for which the ESXi vmkibft module doesn't have a proper check. As a result, iSCSI LUN discovery by using iBFT might fail and cause failure of the ESXi installation on the iSCSI LUN.

This issue is resolved in this release.

PR 3423217: You see vendor name of some Solidigm NVMe devices as Unknown

In the ESXi Host Client, under **Manage > Hardware > PCI Devices**, and in the vSphere Client, under **Host > Configure > Hardware > PCI Devices > All PCI Devices**, you might see the vendor name of some Solidigm NVMe devices as `Unknown`.

This issue is resolved in this release.

PR 3398537: ESXi host fails with a purple diagnostic screen due to an I/O race with an error PSOD @BlueScreen: ASSERT bora/lib/misc/bitvector.c:632

Due to a rare I/O race condition on virtual machines backed by a vSphere Virtual Volume, the ESXi host might fail with a purple diagnostic screen and an error such as `PSOD @BlueScreen: ASSERT bora/lib/misc/bitvector.c:632`.

This issue is resolved in this release.

PR 3371201: The hostd service might generate core dumps during upgrade from ESXi 6.7 to 7.x when SNMP traps are configured

In very rare cases, a missing SNMP port value when SNMP traps are configured during an upgrade from ESXi 6.7 to 7.x, might lead to hostd core dumps.

This issue is resolved in this release.

PR 3352051: Syslog configuration changes in a host profile that you use to provision ESXi host with Auto Deploy stateful install do not persist across reboots

If you change the syslog configuration of a host profile and provision ESXi hosts with that profile by using the Auto Deploy stateful install, changes might not persist after the hosts reboot.

This issue is resolved in this release.

PR 3396010: Controller VMs with direct I/O devices in third-party hyper converged infrastructure environments experience guest kernel soft lockups

A rare race condition between the interrupt virtualization and the VMkernel CPU scheduler in an ESXi host might result in guest kernel soft lockups on controller VMs with direct I/O devices in third-party hyper converged infrastructure environments. The soft locks cause virtual machines in the entire cluster to lose NFS storage connectivity and I/O access.

This issue is resolved in this release.

PR 3359386: If the Latency Sensitivity parameter of a virtual machine is set to High, you cannot add memory to that VM when powered off

If you use the vSphere Client to set the `Latency Sensitivity` parameter of a VM to `High`, attempts to add memory to such a VM when powered off might fail with an error such as `A specified parameter was not correct: spec.memoryAllocation`.

This issue is resolved in this release.

PR 3403867: Setting the CPU limit to 0 makes virtual machines unresponsive

If for any reason you set the CPU limit of running virtual machines to `0`, this causes CPU starvation and the VMs become unresponsive.

This issue is resolved in this release.

PR 3457552: You might see multiple hardware sensor alerts due to a Baseboard Management Controller (BMC) issue

An underlying BMC issue might cause ESXi hardware health monitoring to produce multiple alerts for hardware sensors on ESXi hosts, which you see in the vSphere Client under **Monitor > Tasks and Events**.

This issue is resolved in this release. The fix logs raw sensor data directly from IPMI to provide a data point to debug possible BMC issues that cause false alerts but cannot prevent BMC issues from occuring.

PR 3484794: Restoring the iSCSI configurations on an ESXi host might fail during boot due to stale entries in the ConfigStore database

If the ConfigStore database on an ESXi host has stale iSCSI configurations related to hardware iSCSI adapters, the iSCSI jumpstart might fail and restoring the iSCSI configuration on that host also fails during boot.

This issue is resolved in this release.

PR 3484793: Discovery of iSCSI dynamic targets, LUNs, and datastores fails on ESXi host reboot

In some cases, dynamic discovery of targets in systems that use dynamic discovery addresses for iSCSI configuration might fail. As a result, you do not see iSCSI targets, LUNs, and datastores after a reboot of ESXi hosts. The dynamic discovery of iSCSI targets might also fail when the Challenge-Handshake Authentication Protocol (CHAP) is active on the ESXi host.

This issue is resolved in this release.

PR 3458283: A rare Baseboard Management Controller (BMC) issue might cause some applications to become unresponsive

If an application sends an IPMI request to the BMC while it resets, such requests remain indefinitely pending and cause the applications to become unresponsive.

This issue is resolved in this release. The fix updates the IPMI driver to handle such conditions.

PR 3485174: Guest OS might mark file system read-only after repeated I/O failure which can cause Kubernetes control plane nodes to go into Read-only mode

An issue with the check for max allowed memory address in memory mapping code during I/O processing at virtual SCSI might cause a guest OS on an ESXi host to mark guest file system as read-only. As a result, Kubernetes control plane nodes might go into Read-only mode. In the vmkernel logs, you see multiple error messages such as `failed to pin: I/O error.`

This issue is resolved in this release.

PR 3470731: Unsupported SCSI Read Mode Sense Page commands to a Raw Disk Mapping (RDM) target might cause virtual machines to become unresponsive

A large number of unsupported SCSI Read Mode Sense Page commands to a RDM target from a VM configured with an RDM device might exceed the storage heap and cause both the datastore and the VM to become unresponsive.

This issue is resolved in this release. The fix prevents blocking VM I/O operations by optimizing the handling of unsupported SCSI commands or mode pages. Specifically, in passthrough mode used for RDM devices, the system no longer attempts to process such unsupported commands in a way that consumes storage heap resources.

PR 3398467: vSphere Virtual Volumes daemon fails after converting a VASA provider from external to internal

Due to an issue with handling IDs during an unbind operation for some vSphere API for Storage Awareness (VASA) providers, in some tasks such as converting a VASA provider from external to internal, the vSphere Virtual Volumes daemon vvold might fail as it cannot map unique IDs.

This issue is resolved in this release. With the fix, vvold gracefully handles such conditions and stops the unbind operation with message in the logs instead of failing.

PR 3414590: Snapshot tasks on virtual machines on NVMe/TCP datastores might take much longer than on VMs provisioned on NVMe/FC datastores

When creating or deleting a snapshot on a VM provisioned on datastores backed by NVMe/TCP namespaces, such tasks might take much longer than on VMs provisioned on datastores backed by NVMe/FC namespaces. The issue occurs because the nvmetcp driver handles some specific NVMe commands not in the way the NVMe/TCP target systems expect.

This issue is resolved in this release.

PR 3388843: You cannot activate Kernel DMA Protection on a virtual machine with Windows OS and Intel processor

When virtual Input-Output Memory Management Unit (vIOMMU) is active on a virtual machine with Windows OS and an Intel CPU, you might not be able to activate Kernel DMA Protection.

This issue is resolved in this release. The fix adds `acpi.dmar.enableDMAProtection=TRUE` to the vmx advanced settings that you can use if required.

PR 3469106: ESXi hosts intermittently disconnect from the Active Directory domain or from vCenter

Memory leaks might occur in Likewise during Active Directory operations or if smart card authentication is active on an ESXi host. As a result, Likewise processes might run out of memory and ESXi hosts intermittently disconnect from the Active Directory domain or from vCenter. In the `/var/log/vmkernel.log` file, you see messages similar to:

```
yyyy-mm-dd In(182) vmkernel: cpu72:2110465)uw.2110464 (44739) requires 1024 KB, asked 1024 KB from likewise (792) which has 93112 KB occupied and 72 KB available.
```

```
yyyy-mm-dd In(182) vmkernel: cpu72:2110465)Admission failure in path: host/vim/vmvisor/likewise:lwsmd.2110464:uw.2110464
```

In the `hostd-probe.log` file you see a message such as: `hostd detected to be non-responsive.`

This issue is resolved in this release. The fix adds a system service that monitors Likewise memory usage and restarts relevant services in case memory consumption approaches Likewise limits.

PR 3477734: ESXi host fails with a purple diagnostic screen while activating HClock

If for some reason an ESXi host fails to allocate memory for the activation of the HClock capability, the error handling goes into CPU wait state while it still holds a lock. As a result, the host fails with a purple diagnostic screen, and you see backtraces such as:

```
[0x2b8c]RCU_WaitForGracePeriod@vmkernel#nover stack:
[0xa000]vmk_HashRelease@vmkernel#nover+ stack:
[0xa0000]NetSchedHClkConnect@(netsched_hclk)#<None> stack:
```

This issue is resolved in this release.

PR 3489859: Migration of virtual machines fails with an error "Failed to allocate migration heap" on the source ESXi host

In very rare cases, if a virtual machine powers off before a running migration completes, ESXi might fail to clean up the migration heap. If the memory leak continues over time, the migration heap might be exhausted, and virtual machines cannot migrate from such ESXi hosts.

This issue is resolved in this release.

PR 3499302: If a virtual machine migrates to an ESXi host undergoing NSX update, the Distributed Firewall rule might be detached from that host

During NSX update or upgrade, ESXi hosts go into maintenance mode and the Distributed Resource Scheduler might trigger mass migration of VMs. As a result, vSphere vMotion with the Distributed Firewall rule might fail on some VMs and cause the DFW rule to be detached from the host.

This issue is resolved in this release.

PR 3477772: Encrypted virtual machines with active Change Block Tracking (CBT) might intermittently power off after a rekey operation

Due to a race condition between the VMX and hostd services for a specific VMcrypt-related reconfiguration, encrypted VMs with active CBT might unexpectedly power off during a rekey operation.

This issue is resolved in this release.

PR 3469639: Logging stops on all log files and configured remote host targets on ESXi hosts and hosts might become unresponsive

A rare deadlock situation in the ESXi log daemon vmsyslogd might cause logging to stop on all log files and configured remote host targets on ESXi hosts. As a result, the hosts might become unresponsive. The issue might occur as the result of multiple syslog reloads.

This issue is resolved in this release.

PR 3458045: ESXi hosts intermittently fail with purple diagnostic screen due to a rare race condition

A very rare race condition might lead to accessing an interface address while it is freed from another context. As a result, ESXi hosts might intermittently fail with purple diagnostic screen and an error such as `#PF Exception 14 in world 1001391810:dhclient-uw IP 0x420003562680`.

This issue is resolved in this release.

PR 3398458: ESXi hosts become unresponsive due to pointer blocks cached filling VMFS heap to its limit

Copies of pointer blocks that are part of data transactions between ESXi hosts might be cached in the VMFS heap even after the transactions are completed. Such cached pointer blocks might fill in the heap to its limit and as a result, ESXi hosts become unresponsive from vCenter and eventually virtual machines might go offline.

This issue is resolved in this release.

PR 3390998: ESXi hosts might fail with a purple diagnostic screen due to an incomplete cleanup of a SCSI path after deleting a controller

If a controller is deleted before a device claim process completes, the `namespace` object is removed, but the SCSI Path object remains. When adding a new `namespace`, the SCSI Path might prematurely become claimable, leading to a partially populated `PsaNvmePath` object. If a claim thread picks up that path before initialization, the ESXi host might fail with a purple diagnostic screen with an error such as:`@BlueScreen: #PF Exception 14 in world 1001448541:Cmpl-vmhba66 IP 0x420025354538 addr 0x0`.

This issue is resolved in this release.

PR 3358960: In the vmkernel logs, you see multiple errors from the network interface drivers for an unsupported feature

When the ESXi NetQueue load balancer, which uses load balancing algorithms to manage the vNIC and VMkernel adapter filters, sends a VMK_UPLINK_QUEUE_FEAT_LATENCY request to a nmlx5 driver, you see multiple errors in the vmkernel logs. VMK_UPLINK_QUEUE_FEAT_LATENCY is a software queue feature and if a client request contains this feature, the NIC drivers do not allocate queues but log errors that an unregistered feature is requested.

This issue is resolved in this release. The fix masks VMK_UPLINK_QUEUE_FEAT_LATENCY in requests for queue allocation from NIC drivers.

PR 3441399: You cannot upload virtual machine template of version ESXi 7.0 Update 3 with a DirectPath I/O device to the Content Library

When you create a template from an ESXi 7.0 Update 3 VM with a DirectPath I/O device, the upload to the Content Library fails with a `Null Pointer` exception. In the vSphere Client, you see an error such as `Failed to export OVF package. ThrowableProxy.cause A general runtime error occurred. An error occurred: java.lang.NullPointerException`. In the `cls.log`, you see the error `java.lang.NullPointerException: null`.

This issue is resolved in this release.

PR 3437679: ESXi host fails with a purple diagnostic screen due to mishandling a canceled NVMe write command

In rare cases, a large-size NVMe write command might be canceled due to an I/O timeout but the nvmetcp driver might again complete the command and this causes the ESXi host to fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3393549: Windows and Citrix virtual machines with vGPU intermittently fail with driver-related blue diagnostic screen

Windows and Citrix VMs with a vGPU device might intermittently run out of file handles and fail with a blue diagnostic screen.

This issue is resolved in this release. The fix allows you to increase the number of file handles to 16384 for Windows and Citrix VMs with a vGPU device. For more information, see KB 369633.

PR 3434172: You cannot apply a reverse path filter for virtual machines in promiscuous mode even though /Net/ReversePathFwdCheckPromisc is active

In very specific conditions, after an upgrade of a distributed virtual switch or uninstalling an NSX transport node on an ESXi host with converged distributed virtual switch that contains a port group with active promiscuous mode, you might see some networking issues, including:

1. You cannot apply a reverse path filter for virtual machines in promiscuous mode even though **/Net/ReversePathFwdCheckPromisc** is active.
2. Intermittent packet connectivity issues when using promiscuous mode on a distributed virtual switch with multiple uplinks.

This issue is resolved in this release.

PR 3420117: ESXi hosts become non-responding during a failover

In a failover task, ESXi sends the `INQUIRY page-83` command to the target host to get port parameters but in a ghost LUN configuration some target arrays might provide unformatted output for this command. As a result, the failover task fails and in the kernel logs you see the message `Target completed the Inquiry VPD Page 0x83 request with good status but returned junk data.`

This issue is resolved in this release.

PR 3437311: The intrusion detection and prevention system (IDS/IPS) might report false positives for dropped packets in vSphere reporting tools

In environments with active IDS/IPS, ESXi might report false positives for dropped packets to network monitoring solutions such as Aria Operations. If you deactivate IDS/IPS, the count of dropped packets falls. The issue affects all virtual machines connected to NSX segments.

This issue is resolved in this release.

PR 3398462: Virtual machines residing on a vSphere Virtual Volumes datastore might become inaccessible due to a size reporting issue

An issue in the VASA provider might report an inflated size for the home directory that contains metadata files for a virtual machine and VMFS automatically expands to accommodate the larger size. However, if the VASA provider later reports the correct size, VMFS cannot shrink, and the home directory cannot open. As a result, all VM files stored in the home folder become inaccessible and you cannot access the VMs.

This issue is resolved in this release.

PR 3411044: ESXi host might lose network connectivity due to a very rare issue with the ntg3 driver

A data race in the handling of tx queue full situation in the ntg3 driver might cause in very rare cases the TX queue to stop transmitting packets. As a result, you see either virtual machines or ESXi host management network, or both, lose connectivity. In the vmkernel log of the affected ESXi host, you see messages such as `Uplink: XXXX: Queue 0 of device vmnicX stuck, resetting the device` and/or `Vmxnet3: XXXXX: XXXX, portID(XXXXX): Hang detected.`

This issue is resolved in this release. The fix is part of ntg3 4.1.15.

PR 3407529: Virtual machines with snapshots and active encryption experience higher I/O latency

In rare cases, encrypted VMs with snapshots might experience higher than expected latency. This issue occurs due to unaligned I/O operations that generate excessive metadata requests to the underlying storage and lead to increased latency.

This issue is resolved in this release. To optimize performance, the VMcrypt I/O filter is enhanced to allocate memory in 4K-aligned blocks for both read and write operations. This reduction in metadata overhead significantly improves overall I/O performance.

PR 3410295: You see gaps in the collection of metrics for some virtual machines

Due to a time sync issue, collection of data for some VMs might fail and you do not see any performance data in platforms such as Aria Operations. In the */var/run/log/vobd.log* on the ESXi host, you see errors such as: `1149:2024-06-11T05:01:11.250Z: [ClockCorrelator] 7826272852729us: [vob.clock.correction.adjtime.sync] system clock synchronized to upstream time servers`

This issue is resolved in this release. The fix caches results from Stats Registry queries with selected dynamic counters to make sure metrics are consistent.

PR 3401554: vSAN Original Storage Architecture (OSA) virtual machines with large-sized VMDKs might experience performance degradation or become inaccessible

In vSAN OSA environments of version 8.0 and later, VMDK objects with a large amount of used capacity, such as close to the maximum of 62 TB, might overload the scrubber, which leads to a race condition that might cause such objects to experience performance degradation or become inaccessible.

This issue is resolved in this release.

PR 3359530: ESXi hosts fail with purple diagnostic screen due to a pNIC driver memory overload

In a rare situation when memory-intensive workloads that fragment system memory run in parallel with throughput-intensive workloads on a virtual switch configured with 9000 MTU or more, ESXi hosts might fail with a purple diagnostic screen. As a result, power-on virtual machines become temporarily unavailable. The issue occurs because memory allocation requests from the pNIC driver overload the memory subsystem with a growing networking packet heap, which causes ESXi to fail with a stack trace at `/var/cores/` such as:

```
NMI_Interrupt@vmkernel#nover+0x561
IDTNMIWork@vmkernel#nover+0x7f
Int2_NMI@vmkernel#nover+0x19
gate_entry@vmkernel#nover+0x68
Timer_GetCycles@vmkernel#nover+0x2
SP_WaitLockIRQ@vmkernel#nover+0xd5
SPLockIRQWork@vmkernel#nover+0x3e
Heap_AlignWithTimeoutAndRA@vmkernel#nover+0xea
Pkt_AllocHandleWithSize@vmkernel#nover+0x165
Pkt_AllocWithFlags@vmkernel#nover+0xd
vmk_PktAllocForDMAEngine@vmkernel#nover+0x46
```

This issue is resolved in this release. With the fix, you can reserve enough memory for the pNIC driver using the command `esxcli system settings kernel set -s netPktJumboSlabMinSize -v <MEMORY_SIZE_TO_RESERVE_IN_MB>` . To define the amount of memory you need to reserve, use this formula: `reservation size = (numPnics * numRxQueues * (rxRingSize + 64) + numPcpus *256) * 10KB`. For example, for an ESXi host with 72 PCPUs and 4 PNICs with 10 queues of ring size set to 4K each, the reservation is about 2048 MB.

PR 3412449: Remediation of ESXi hosts might fail due to a timeout in the update of the VMware-VM-Tools component

While upgrading ESXi hosts by using vSphere Lifecycle Manager, remediation of the VMware-VM-Tools component might occasionally fail due to a timeout. The issue occurs when the update process takes longer than the timeout setting of 30 sec for the VMware-VM-Tools component.

This issue is resolved in this release. The fix increases the timeout limit to 120 sec.

PR 3400360: VMFS6 automatic UNMAP feature might fail to reclaim filesystem space beyond 250GB

In certain cases, when you delete a filesystem space of more than 250GB on a VMFS6 volume, for example 1 TB, if the volume has no active references such as active VMs, then the VMFS6 automatic UNMAP feature might fail to reclaim the filesystem space beyond 250GB.

This issue is resolved in this release.

PR 3355390: An ESXi host fails with a purple diagnostic screen and message @BlueScreen: NMI IPI: Panic requested by another PCPU

If firewall rules in your environment result in packets moving across multiple portsets, a race condition might cause software locks to end in a deadlock. As a result, an ESXi host might fail with a purple diagnostic screen and message `@BlueScreen: NMI IPI: Panic requested by another PCPU.`

This issue is resolved in this release.

PR 3404507: ESXi hosts might fail with purple diagnostic screen due to a rare memory allocation error

If a VM power-on fails, a function that allocates memory on the heap might not free certain allocations and cause a memory leak. As a result, the ESXi host fails with a purple diagnostic screen in `World_DestroyHeap` with `NOT_IMPLEMENTED bora/vmkernel/main/world.c:2293` and `Unable to complete wait for non-empty heap` errors.

This issue is resolved in this release. The fix makes sure a cleanup function runs to free allocations to prevent the issue.

PR 3406156: Extracting a vSphere Lifecycle Manager image from an existing ESXi host might fail after a kernel configuration change

Each update of the kernel configuration also triggers an update to the `/bootbank/useropts.gz` file, but due to a rare issue, the `basemisc.tgz` might not contain the default `useropts` file after such an update. As a result, when attempting to extract a vSphere Lifecycle Manager image from an existing ESXi host, the absence of the default `useropts` file leads to failure to create the `esx-base.vib` file and the operational also fails.

This issue is resolved in this release.

PR 3396464: A lost cleanup callback might cause purple diagnostic screen failures in vSAN clusters with Remote Direct Memory Access (RDMA)

In Express Storage Architecture (ESA) vSAN clusters with active RDMA, a rare issue with a lost cleanup callback might cause a purple diagnostic screen failure with a message such as `Failed to wait for object exit.` The issue is specific to RDMA use in vSAN.

This issue is resolved in this release.

PR 3398279: Creating a vSAN File Service fails when you use IPs within the 172.17.0.0/16 range as mount points

Prior to vSphere 7.0 Update 3v, you must change your network configuration in cases when the specified file service network overlaps with the Docker default internal network 172.17.0.0/16. As a result, in the network configuration step of the File Service activation workflow, when you enter a subnet with 172.17.**.**, you see a warning and you cannot create vSAN File Services.

This issue is resolved in this release. The fix routes traffic to the correct endpoint to avoid possible conflicts. The fix is in the vSAN File Service Virtual Machine, and if you upgrade the file service to 7.0 Update 3v, you can ignore the conflict warning and continue the file service activation with subnet 172.17.0.0/16.

PR 3365863: ESXi hosts might fail with a purple diagnostic screen during high volume of outstanding I/O requests combined with slow storage performance

Under heavy I/O loads, a bug in the ESXi storage stack can cause an ESXi host to fail with a purple diagnostics screen if the storage cannot process the I/O requests quickly and some virtual machines on the ESXi host start issuing I/O resets.

This issue is resolved in this release.

PR 3364569: If a NVMe/TCP driver fails to process an I/O command, an ESXi host might disconnect from a storage array

If your ESXi hosts connect to storage arrays and perform read/write operations by using NVMe/TCP connections, when a NVMe/TCP driver fails to process an I/O command, ESXi might cancel the process with an abort command. As a result, an ESXi host might disconnect from a storage array and end previous I/O queues.

This issue is resolved in this release.

PR 3332717: An ESXi hosts might fail with a purple diagnostic screen during a file close on a NFS41 datastore

A file close on a NFS41 datastore might lead to memory corruption in a layer common across file systems. A subsequent file open on an NFSv3 datastore picks up the same memory zone. As a result, the ESXi host might fail with a purple diagnostic screen with a backtrace similar to:

```
NFSDestroySchedQueue NFS
Sched_DestroySchedQueue
NFSVolume_DestroySchedQHandle
```

This issue is resolved in this release.

PR 3352007: ESXi hosts might fail with a purple diagnostics screen and with errors for CpuSchedWait() and FS3_ReportCorruption() in the backtrace

In a data corruption scenario, the corruption report routine requires to load the VMFS datastore volume header metadata and perform a validation. In very rare cases, a spinlock might prevent reading this metadata and as a result, ESXi hosts might fail with a purple diagnostics screen. In the backtrace, you see errors for `CpuSchedWait()` and `FS3_ReportCorruption()`.

This issue is resolved in this release. The fix enhances the data corruption report routine to allow skipping the read on the volume header metadata for such rare cases.

PR 3367834: A fault tolerance secondary virtual machine might restart by accident

In very rare cases, a fault tolerance secondary VM might restart unexpectedly while other fault tolerance VMs power off or migrate from the ESXi host.

This issue is resolved in this release.

PR 3389767: During a vSphere vMotion migration of a fault tolerant Primary VM with encryption, the migration task might fail and vSphere FT failover occurs

In rare cases, the encryption key package might not be sent or received correctly during a vSphere vMotion migration of a fault tolerant Primary VM with encryption, and as a result the migration task fails and vSphere FT failover occurs.

This issue is resolved in this release. The fix sends the encryption key at the end of the vSphere FT checkpoint to avoid errors.

PR 3382561: Virtual machines that share the same encryption key are randomly locked after the ESXi host reboots

When cloned from a single VM, several VMs can share the same encryption key. After an ESXi host reboot, each key of such VMs is added to the key cache, but while the first key addition succeeds, subsequent additions fail because the key already exists in the cache, and the key is removed. As a result, such VMs become locked.

This issue is resolved in this release.

ESXi-7.0U3sv-24723868-standard

The following VMware Tools ISO images are bundled with ESXi 7.0 Update 3v:

- **windows.iso**: VMware Tools 12.5.1 supports the following 64-bit Windows versions:- Windows 7 SP1 or Windows Server 2008 R2 SP1 and later.
  For **windows.iso** support for 32-bit Windows versions: Windows 7 SP1 or Windows Server 2008 R2 SP1 and later, refer to VMware Tools 12.4.5 Release Notes.
  VMware Tools 12.5.0 provides support for Windows Server 2025, but make sure your system supports Windows 2025 if you plan to use Windows 2025 as a guest OS on virtual machines. For more information, see Installing Windows Server 2025 on a VMware Virtual Machine.
- **linux.iso**: VMware Tools 10.3.25 ISO image for Linux OS with **glibc** 2.11 or later.

The following VMware Tools ISO images are available for download:

- VMware Tools 11.0.6:
  - **windows.iso**: for Windows Vista (SP2) and Windows Server 2008 Service Pack 2 (SP2).
- VMware Tools 10.0.12:
  - **winPreVista.iso**: for Windows 2000, Windows XP, and Windows 2003.
  - **linuxPreGLibc25.iso**: supports Linux guest operating systems earlier than Red Hat Enterprise Linux (RHEL) 5, SUSE Linux Enterprise Server (SLES) 11, Ubuntu 7.04, and other distributions with **glibc** version earlier than 2.5.
- **solaris.iso**: VMware Tools image 10.3.10 for Solaris.
- **darwin.iso**: Supports Mac OS X versions 10.11 and later. VMware Tools 12.1.0 was the last regular release for macOS. For more details, see VMware knowledge base article 88698.

Follow the procedures listed in the following documents to download VMware Tools for platforms not bundled with ESXi:

- Updating VMware Tools
- VMware Tools for hosts provisioned with Auto Deploy
- What Every vSphere Admin Must Know About VMware Tools
- Earlier versions of VMware Tools
- VMware Tools 12.5.1 Release Notes

PR 3408358: Security scans on ESXi hosts with OpenSSH 8.8 show multiple CVEs

When for some reason you need to activate OpenSSH on an ESXi host, if the OpenSSH version is 8.8 and you run a security scan, you might see multiple CVEs.

This issue is resolved in this release. The fix updates OpenSSH to version 9.3p2 and backports security fixes from later versions: CVE-2024-6387, CVE-2023-51385, CVE-2023-51384, CVE-2023-48795, CVE-2023-38408. The version string is updated to **OpenSSH_9.3p2 vmw9.8p1** to indicate the backported patches.

The following VMware Tools ISO images are bundled with ESXi 7.0 Update 3v:

- **windows.iso**: VMware Tools 12.5.1 supports the following 64-bit Windows versions:- Windows 7 SP1 or Windows Server 2008 R2 SP1 and later.
  For **windows.iso** support for 32-bit Windows versions: Windows 7 SP1 or Windows Server 2008 R2 SP1 and later, refer to VMware Tools 12.4.5 Release Notes.
  VMware Tools 12.5.0 provides support for Windows Server 2025, but make sure your system supports Windows 2025 if you plan to use Windows 2025 as a guest OS on virtual machines. For more information, see Installing Windows Server 2025 on a VMware Virtual Machine.
- **linux.iso**: VMware Tools 10.3.25 ISO image for Linux OS with **glibc** 2.11 or later.

The following VMware Tools ISO images are available for download:

- VMware Tools 11.0.6:
  - **windows.iso**: for Windows Vista (SP2) and Windows Server 2008 Service Pack 2 (SP2).
- VMware Tools 10.0.12:
  - **winPreVista.iso**: for Windows 2000, Windows XP, and Windows 2003.
  - **linuxPreGLibc25.iso**: supports Linux guest operating systems earlier than Red Hat Enterprise Linux (RHEL) 5, SUSE Linux Enterprise Server (SLES) 11, Ubuntu 7.04, and other distributions with **glibc** version earlier than 2.5.
- **solaris.iso**: VMware Tools image 10.3.10 for Solaris.
- **darwin.iso**: Supports Mac OS X versions 10.11 and later. VMware Tools 12.1.0 was the last regular release for macOS. For more details, see VMware knowledge base article 88698.

Follow the procedures listed in the following documents to download VMware Tools for platforms not bundled with ESXi:

- Updating VMware Tools
- VMware Tools for hosts provisioned with Auto Deploy
- What Every vSphere Admin Must Know About VMware Tools
- Earlier versions of VMware Tools
- VMware Tools 12.5.1 Release Notes

PR 3408358: Security scans on ESXi hosts with OpenSSH 8.8 show multiple CVEs

When for some reason you need to activate OpenSSH on an ESXi host, if the OpenSSH version is 8.8 and you run a security scan, you might see multiple CVEs.

This issue is resolved in this release. The fix updates OpenSSH to version 9.3p2 and backports security fixes from later versions: CVE-2024-6387, CVE-2023-51385, CVE-2023-51384, CVE-2023-48795, CVE-2023-38408. The version string is updated to **OpenSSH_9.3p2 vmw9.8p1** to indicate the backported patches.

ESXi 7.0 U3v - 24723872

Name	ESXi
Version	ESXi 7.0 U3v - 24723872
Release Date	May 20, 2025
Category	BugFix
Affected Components	• ESXi Component - core ESXi • ESXi Install/Upgrade • ESXi Tools Component
PRs Fixed	3406035, 3477734, 3489859, 3352051, 3457552, 3485174, 3469639, 3470731, 3485586, 3484794, 3484793, 3484786, 3477773, 3469106, 3477257, 3476746, 3475049, 3454755, 3469189, 3466996, 3458045, 3435833, 3447991, 3443815, 3432572, 3432690, 3441101, 3404668, 3434172, 3437311, 3371201, 3367834, 3398462, 3410295, 3390998, 3398458, 3388843, 3398467, 3430801, 3408807, 3420117, 3417327, 3423849, 3417227, 3417328, 3404126, 3408129, 3408008, 3408126, 3398534, 3400360, 3406033, 3398361, 3398279, 3407212, 3411695, 3396010, 3412537, 3352007, 3404202, 3402976, 3396464, 3407529, 3408143, 3336865, 3403867, 3389767, 3366075, 3365863, 3404507, 3403906, 3405760, 3401554, 3398537, 3355390, 3359530, 3393549, 3367426, 3359386, 3382561, 3358960, 3422040, 3412449, 3400844, 3365671, 3411044, 3437679, 3414590, 3364569
Related CVE numbers	CVE-2025-41226, CVE-2025-41227, CVE-2025-41228

This patch resolves the issues listed in the ESXi-7.0U3v-24723872-standard image profile.

ESXi 7.0 U3sv - 24723868

Name	ESXi
Version	ESXi 7.0 U3sv - 24723868
Release Date	May 20, 2025
Category	Security
Affected Components	• ESXi Component - core ESXi • ESXi Install/Upgrade • ESXi Tools Component
PRs Fixed	3452679, 3488111, 3456430, 3450561, 3482267, 3479599, 3484230, 3476566, 3452717, 3432584, 3475105, 3470206, 3452699, 3435458, 3404661, 3400981, 3444626, 3469216, 3454671, 3469563, 3457662, 3447985, 3443017, 3432572, 3432690, 3404668, 3430751, 3400984, 3406922, 3430750, 3406923, 3425364, 3398141, 3406188, 3400967, 3430766, 3316536, 3408358, 3408125, 3390665, 3411970, 3412457, 3400130, 3404669, 3386280, 3494213, 3409318
Related CVE numbers	CVE-2025-41226, CVE-2025-41227, CVE-2025-41228

This patch resolves the issues listed in the ESXi-7.0U3sv-24723868-standard image profile.

Known Issues

vSAN Issues

When rebooting a vSAN host, other hosts in the vSAN cluster enter a partitioned state

During ESXi shutdown, hosts in a vSAN cluster can enter a state where they can transmit but not receive data. Depending of the exact timing and duration of this state, this state can lead to unexpected role changes in the vSAN distributed cluster membership, monitoring, and directory service (CMMDS). Consequently, vSAN hosts might continually attempt to reform a cluster with the rebooting host or send CMMDS updates through the rebooting host, which is unresponsive to incoming traffic. As a result, in the vSAN Health monitoring you see `vSAN Cluster Partition` alarms.

Workaround: Before rebooting a vSAN host, identify all vmknics on the host with tags `VSAN` , `VSANWitness` , or `VSANExternal` , take note of which vSAN tag is used on each vmknic, and remove the tags. After rebooting, reapply the tags for vSAN traffic by type and vmknic.

Known Issues from Previous Releases

vSphere Cluster Services Issues

You see compatibility issues in new vCLS VMs deployed in vSphere 7.0 Update 3 environment

The default name for new vCLS VMs deployed in vSphere 7.0 Update 3 environment uses the pattern vCLS-UUID. vCLS VMs created in earlier vCenter Server versions continue to use the pattern vCLS (n). Since the use of parenthesis () is not supported by many solutions that interoperate with vSphere, you might see compatibility issues.

Workaround: Reconfigure vCLS by using retreat mode after updating to vSphere 7.0 Update 3.

Installation, Upgrade, and Migration Issues

The vCenter Upgrade/Migration pre-checks fail with "Unexpected error 87"

The vCenter Server Upgrade/Migration pre-checks fail when the Security Token Service (STS) certificate does not contain a Subject Alternative Name (SAN) field. This situation occurs when you have replaced the vCenter 5.5 Single Sign-On certificate with a custom certificate that has no SAN field, and you attempt to upgrade to vCenter Server 7.0. The upgrade considers the STS certificate invalid and the pre-checks prevent the upgrade process from continuing.

Workaround: Replace the STS certificate with a valid certificate that contains a SAN field then proceed with the vCenter Server 7.0 Upgrade/Migration.

Corrupted VFAT partitions from a vSphere 6.7 environment might cause upgrades to ESXi 7.x to fail

Due to corrupted VFAT partitions from a vSphere 6.7 environment, repartitioning the boot disks of an ESXi host might fail during an upgrade to ESXi 7.x. As a result, you might see the following errors:

When upgrading to ESXi 7.0 Update 3l, the operation fails with a purple diagnostic screen and/or an error such as:

- `An error occurred while backing up VFAT partition files before re-partitioning: Failed to calculate size for temporary Ramdisk: <error>.`
- `An error occurred while backing up VFAT partition files before re-partitioning: Failed to copy files to Ramdisk: <error>.`
  If you use an ISO installer, you see the errors, but no purple diagnostic screen.

When upgrading to an ESXi 7.x version earlier than 7.0 Update 3l, you might see:

- Logs such as `ramdisk (root) is full` in the `vmkwarning.log` file.
- Unexpected rollback to ESXi 6.5 or 6.7 on reboot.
- The `/bootbank` ,`/altbootbank` , and ESX-OSData partitions are not present.

Workaround: You must first remediate the corrupted partitions before completing the upgrade to ESXi 7.x. For more details, see VMware knowledge base article 91136.

Problems upgrading to vSphere 7.0 with pre-existing CIM providers

After upgrade, previously installed 32-bit CIM providers stop working because ESXi requires 64-bit CIM providers. Customers may lose management API functions related to CIMPDK, NDDK (native DDK), HEXDK, VAIODK (IO filters), and see errors related to **uwglibc** dependency.

The syslog reports module missing, "32 bit shared libraries not loaded."

Workaround: There is no workaround. The fix is to download new 64-bit CIM providers from your vendor.

Installation of 7.0 Update 1 drivers on ESXi 7.0 hosts might fail

You cannot install drivers applicable to ESXi 7.0 Update 1 on hosts that run ESXi 7.0 or 7.0b.

The operation fails with an error, such as:

```
VMW_bootbank_qedrntv_3.40.4.0-12vmw.701.0.0.xxxxxxx requires vmkapi_2_7_0_0, but the
requirement cannot be satisfied within the ImageProfile. Please refer to the log file for
more details.
```

Workaround: Update the ESXi host to 7.0 Update 1. Retry the driver installation.

UEFI booting of ESXi hosts might stop with an error during an update to ESXi 7.0 Update 2 from an earlier version of ESXi 7.0

If you attempt to update your environment to 7.0 Update 2 from an earlier version of ESXi 7.0by using vSphere Lifecycle Manager patch baselines, UEFI booting of ESXi hosts might stop with an error such as:

```
Loading /boot.cfgFailed to load crypto64.efiFatal error: 15 (Not found)
```

Workaround: For more information, see VMware knowledge base articles 83063 and 83107 .

If legacy VIBs are in use on an ESXi host, vSphere Lifecycle Manager cannot extract a desired software specification to seed to a new cluster

With vCenter Server 7.0 Update 2, you can create a new cluster by importing the desired software specification from a single reference host. However, if legacy VIBs are in use on an ESXi host, vSphere Lifecycle Manager cannot extract in the vCenter Server instance where you create the cluster a reference software specification from such a host. In the `/var/log/lifecycle.log` , you see messages such as:

```
020-11-11T06:54:03Z lifecycle: 1000082644: HostSeeding:499
ERROR Extract depot failed: Checksum doesn't match. Calculated
5b404e28e83b1387841bb417da93c8c796ef2497c8af0f79583fd54e789d8826, expected:
0947542e30b794c721e21fb595f1851b247711d0619c55489a6a8cae6675e796 2020-11-11T06:54:04Z
lifecycle: 1000082644: imagemanagerctl:366 ERROR Extract depot failed.
2020-11-11T06:54:04Z lifecycle: 1000082644: imagemanagerctl:145 ERROR [VibChecksumError]
```

Workaround: Follow the steps described in VMware knowledge base article 83042.

You see a short burst of log messages in the syslog.log after every ESXi boot

After updating to ESXi 7.0 Update 2, you might see a short burst of log messages after every ESXi boot.

Such logs do not indicate any issue with ESXi and you can ignore these messages. For example:

```
2021-01-19T22:44:22Z watchdog-vaai-nasd: '/usr/lib/vmware/nfs/bin/vaai-nasd -f'
exited after 0 seconds (quick failure 127) 12021-01-19T22:44:22Z watchdog-vaai-

```

Workaround: None

You see warning messages for missing VIBs in vSphere Quick Boot compatibility check reports

After you upgrade to ESXi 7.0 Update 2, if you check vSphere Quick Boot compatibility of your environment by using the `/usr/lib/vmware/loadesx/bin/loadESXCheckCompat.py` command, you might see some warning messages for missing VIBs in the shell. For example:

```
Cannot find VIB(s) ... in the given VIB collection.Ignoring missing reserved VIB(s) ...,
they are removed from reserved VIB IDs.
```

Such warnings do not indicate a compatibility issue.

Workaround: The missing VIB messages can be safely ignored and do not affect the reporting of vSphere Quick Boot compatibility. The final output line of the `loadESXCheckCompat` command unambiguously indicates if the host is compatible.

Auto bootstrapping a cluster that you manage with a vSphere Lifecycle Manager image fails with an error

If you attempt auto bootstrapping a cluster that you manage with a vSphere Lifecycle Manager image to perform a stateful install and overwrite the VMFS partitions, the operation fails with an error. In the support bundle, you see messages such as:

```
2021-02-11T19:37:43Z Host Profiles[265671 opID=MainThread]: ERROR:
EngineModule::ApplyHostConfig. Exception: [Errno 30] Read-only file system
```

Workaround: Follow vendor guidance to clean the VMFS partition in the target host and retry the operation. Alternatively, use an empty disk. For more information on the disk-partitioning utility on ESXi, see VMware knowledge base article 1036609.

Upgrades to ESXi 7.x from 6.5.x and 6.7.0 by using ESXCLI might fail due to a space limitation

Upgrades to ESXi 7.x from 6.5.x and 6.7.0 by using the `esxcli software profile update` or `esxcli software profile install` ESXCLI commands might fail, because the ESXi bootbank might be less than the size of the image profile. In the ESXi Shell or the PowerCLI shell, you see an error such as:

```
[InstallationError]
 The pending transaction requires 244 MB free space, however the maximum supported size is 239 MB.
 Please refer to the log file for more details.
```

The issue also occurs when you attempt an ESXi host upgrade by using the ESXCLI commands `esxcli software vib update` or `esxcli software vib install`.

Workaround: You can perform the upgrade in two steps, by using the `esxcli software profile update` command to update ESXi hosts to ESXi 6.7 Update 1 or later, and then update to 7.0 Update 1c. Alternatively, you can run an upgrade by using an ISO image and the vSphere Lifecycle Manager.

You cannot migrate linked clones across vCenter Servers

If you migrate a linked clone across vCenter Servers, operations such as power on and delete might fail for the source virtual machine with an `Invalid virtual machine state` error.

Workaround: Keep linked clones on the same vCenter Server as the source VM. Alternatively, promote the linked clone to full clone before migration.

Migration across vCenter Servers of virtual machines with many virtual disks and snapshot levels to a datastore on NVMe over TCP storage might fail

Migration across vCenter Servers of virtual machines with more than 180 virtual disks and 32 snapshot levels to a datastore on NVMe over TCP storage might fail. The ESXi host preemptively fails with an error such as `The migration has exceeded the maximum switchover time of 100 second(s).`

Workaround: None

A virtual machine with enabled Virtual Performance Monitoring Counters (VPMC) might fail to migrate between ESXi hosts

If you try to migrate a virtual machine with enabled VPMC by using vSphere vMotion, the operation might fail if the target host is using some of the counters to compute memory or performance statistics. The operation fails with an error such as `A performance counter used by the guest is not available on the host CPU.`

Workaround: Power off the virtual machine and use cold migration. For more information, see VMware knowledge base article 81191.

If a live VIB install, upgrade, or remove operation immediately precedes an interactive or scripted upgrade to ESXi 7.0 Update 3 by using the installer ISO, the upgrade fails

When a VIB install, upgrade, or remove operation immediately precedes an interactive or scripted upgrade to ESXi 7.0 Update 3 by using the installer ISO, the ConfigStore might not keep some configurations of the upgrade. As a result, ESXi hosts become inaccessible after the upgrade operation, although the upgrade seems successful. To prevent this issue, the ESXi 7.0 Update 3 installer adds a temporary check to block such scenarios. In the ESXi installer console, you see the following error message: `Live VIB installation, upgrade or removal may cause subsequent ESXi upgrade to fail when using the ISO installer.`

Workaround: Use an alternative upgrade method to avoid the issue, such as using ESXCLI or the vSphere Lifecycle Manager.

Smart Card and RSA SecurID authentication might stop working after upgrading to vCenter Server 7.0

If you have configured vCenter Server for either Smart Card or RSA SecurID authentication, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057 before starting the vSphere 7.0 upgrade process. If you do not perform the workaround as described in the KB, you might see the following error messages and Smart Card or RSA SecurID authentication does not work.

"Smart card authentication may stop working. Smart card settings may not be preserved, and smart card authentication may stop working."

or

"RSA SecurID authentication may stop working. RSA SecurID settings may not be preserved, and RSA SecurID authentication may stop working."

Workaround: Before upgrading to vSphere 7.0, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057.

The vlanid property in custom installation scripts might not work

If you use a custom installation script that sets the `vlanid` property to specify a desired VLAN, the property might not take effect on newly installed ESXi hosts. The issue occurs only when a physical NIC is already connected to DHCP when the installation starts. The `vlanid` property works properly when you use a newly connected NIC.

Workaround: Manually set the VLAN from the Direct Console User Interface after you boot the ESXi host. Alternatively, disable the physical NIC and then boot the host.

HPE servers with Trusted Platform Module (TPM) boot, but remote attestation fails

Some HPE servers do not have enough event log space to properly finish TPM remote attestation. As a result, the VMkernel boots, but remote attestation fails due to the truncated log.

Workaround: None.

Upgrading a vCenter Server with an external Platform Services Controller from 6.7u3 to 7.0 fails with VMAFD error

When you upgrade a vCenter Server deployment using an external Platform Services Controller, you converge the Platform Services Controller into a vCenter Server appliance. If the upgrade fails with the error `install.vmafd.vmdir_vdcpromo_error_21` , the VMAFD firstboot process has failed. The VMAFD firstboot process copies the VMware Directory Service Database (data.mdb) from the source Platform Services Controller and replication partner vCenter Server appliance.

Workaround: Disable TCP Segmentation Offload (TSO) and Generic Segmentation Offload (GSO) on the Ethernet adapter of the source Platform Services Controller or replication partner vCenter Server appliance before upgrading a vCenter Server with an external Platform Services Controller. See Knowledge Base article: https://kb.vmware.com/s/article/74678

Smart card and RSA SecurID settings may not be preserved during vCenter Server upgrade

Authentication using RSA SecurID will not work after upgrading to vCenter Server 7.0. An error message will alert you to this issue when attempting to login using your RSA SecurID login.

Workaround: Reconfigure the smart card or RSA SecureID.

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with network error message

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with the error message `IP already exists in the network.` This prevents the migration process from configuring the network parameters on the new vCenter Server appliance. For more information, examine the log file: `/var/log/vmware/upgrade/UpgradeRunner.log`

Workaround:

1. Verify that all Windows Updates have been completed on the source vCenter Server for Windows instance, or disable automatic Windows Updates until after the migration finishes.
2. Retry the migration of vCenter Server for Windows to vCenter Server appliance 7.0.

When you configure the number of virtual functions for an SR-IOV device by using the max_vfs module parameter, the changes might not take effect

In vSphere 7.0, you can configure the number of virtual functions for an SR-IOV device by using the Virtual Infrastructure Management (VIM) API, for example, through the vSphere Client. The task does not require reboot of the ESXi host. After you use the VIM API configuration, if you try to configure the number of SR-IOV virtual functions by using the `max_vfs` module parameter, the changes might not take effect because they are overridden by the VIM API configuration.

Workaround: None. To configure the number of virtual functions for an SR-IOV device, use the same method every time. Use the VIM API or use the `max_vfs` module parameter and reboot the ESXi host.

Upgraded vCenter Server appliance instance does not retain all the secondary networks (NICs) from the source instance

During a major upgrade, if the source instance of the vCenter Server appliance is configured with multiple secondary networks other than the VCHA NIC, the target vCenter Server instance will not retain secondary networks other than the VCHA NIC. If the source instance is configured with multiple NICs that are part of VDS port groups, the NIC configuration will not be preserved during the upgrade. Configurations for vCenter Server appliance instances that are part of the standard port group will be preserved.

Workaround: None. Manually configure the secondary network in the target vCenter Server appliance instance.

After upgrading or migrating a vCenter Server with an external Platform Services Controller, users authenticating using Active Directory lose access to the newly upgraded vCenter Server instance

After upgrading or migrating a vCenter Server with an external Platform Services Controller, if the newly upgraded vCenter Server is not joined to an Active Directory domain, users authenticating using Active Directory will lose access to the vCenter Server instance.

Workaround: Verify that the new vCenter Server instance has been joined to an Active Directory domain. See Knowledge Base article: https://kb.vmware.com/s/article/2118543

Migrating a vCenter Server for Windows with an external Platform Services Controller using an Oracle database fails

If there are non-ASCII strings in the Oracle events and tasks table the migration can fail when exporting events and tasks data. The following error message is provided: UnicodeDecodeError

Workaround: None.

After an ESXi host upgrade, a Host Profile compliance check shows non-compliant status while host remediation tasks fail

The non-compliant status indicates an inconsistency between the profile and the host.

This inconsistency might occur because ESXi 7.0 does not allow duplicate claim rules, but the profile you use contains duplicate rules. For example, if you attempt to use the Host Profile that you extracted from the host before upgrading ESXi 6.5 or ESXi 6.7 to version 7.0 and the Host Profile contains any duplicate claim rules of system default rules, you might experience the problems.

Workaround:

1. Remove any duplicate claim rules of the system default rules from the Host Profile document.
2. Check the compliance status.
3. Remediate the host.
4. If the previous steps do not help, reboot the host.

Error message displays in the vCenter Server Management Interface

After installing or upgrading to vCenter Server 7.0, when you navigate to the Update panel within the vCenter Server Management Interface, the error message "Check the URL and try again" displays. The error message does not prevent you from using the functions within the Update panel, and you can view, stage, and install any available updates.

Workaround: None.

Security Features Issues

Turn off the Service Location Protocol service in ESXi, slpd, to prevent potential security vulnerabilities

Some services in ESXi that run on top of the host operating system, including slpd, the CIM object broker, sfcbd, and the related openwsmand service, have proven security vulnerabilities. VMware has addressed all known vulnerabilities in VMSA-2019-0022 and VMSA-2020-0023, and the fixes are part of the vSphere 7.0 Update 2 release. While sfcbd and openwsmand are disabled by default in ESXi, slpd is enabled by default and you must turn it off, if not necessary, to prevent exposure to a future vulnerability after an upgrade.

Workaround: To turn off the slpd service, run the following PowerCLI commands:

```
$ Get-VMHost | Get-VmHostService | Where-Object {$_.key -eq "slpd"} | Set-VMHostService -policy "off"$ Get-VMHost | Get-VmHostService | Where-Object {$_.key -eq "slpd"} | Stop-VMHostService -Confirm:$false
```

Alternatively, you can use the command `chkconfig slpd off && /etc/init.d/slpd stop`.

The openwsmand service is not on the ESXi services list and you can check the service state by using the following PowerCLI commands:

```
$esx=(Get-EsxCli -vmhost xx.xx.xx.xx -v2)$esx.system.process.list.invoke() | where CommandLine -like '*openwsman*' | select commandline
```

In the ESXi services list, the sfcbd service appears as sfcbd-watchdog.

For more information, see VMware knowledge base articles 76372 and 1025757.

Encrypted virtual machine fails to power on when HA-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled HA on the Trusted Cluster and one or more hosts in the cluster fails attestation, an encrypted virtual machine cannot power on.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Encrypted virtual machine fails to power on when DRS-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled DRS on the Trusted Cluster and one or more hosts in the cluster fails attestation, DRS might try to power on an encrypted virtual machine on an unattested host in the cluster. This operation puts the virtual machine in a locked state.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Migrating or cloning encrypted virtual machines across vCenter Server instances fails when attempting to do so using the vSphere Client

If you try to migrate or clone an encrypted virtual machine across vCenter Server instances using the vSphere Client, the operation fails with the following error message: "The operation is not allowed in the current state."

Workaround: You must use the vSphere APIs to migrate or clone encrypted virtual machines across vCenter Server instances.

Networking Issues

Reduced throughput in networking performance on Intel 82599/X540/X550 NICs

The new queue-pair feature added to ixgben driver to improve networking performance on Intel 82599EB/X540/X550 series NICs might reduce throughput under some workloads in vSphere 7.0 as compared to vSphere 6.7.

Workaround: To achieve the same networking performance as vSphere 6.7, you can disable the queue-pair with a module parameter. To disable the queue-pair, run the command:

```
# esxcli system module parameters set -p "QPair=0,0,0,0..." -m ixgben
```

After running the command, reboot.

One or more I/O devices do not generate interrupts when the AMD IOMMU is in use

If the I/O devices on your ESXi host provide more than a total of 512 distinct interrupt sources, some sources are erroneously assigned an interrupt-remapping table entry (IRTE) index in the AMD IOMMU that is greater than the maximum value. Interrupts from such a source are lost, so the corresponding I/O device behaves as if interrupts are disabled.

Workaround: Use the ESXCLI command `esxcli system settings kernel set -s iovDisableIR -v true` to disable the AMD IOMMU interrupt remapper. Reboot the ESXi host so that the command takes effect.

When you set auto-negotiation on a network adapter, the device might fail

In some environments, if you set link speed to auto-negotiation for network adapters by using the command `esxcli network nic set -a -n vmmicx`, the devices might fail and reboot does not recover connectivity. The issue is specific to a combination of some Intel X710/X722 network adapters, a SFP+ module and a physical switch, where auto-negotiate speed/duplex scenario is not supported.

Workaround: Make sure you use an Intel-branded SFP+ module. Alternatively, use a Direct Attach Copper (DAC) cable.

Solarflare x2542 and x2541 network adapters configured in 1x100G port mode achieve throughput of up to 70Gbps in a vSphere environment

vSphere 7.0 Update 2 supports Solarflare x2542 and x2541 network adapters configured in 1x100G port mode. However, you might see a hardware limitation in the devices that causes the actual throughput to be up to some 70Gbps in a vSphere environment.

Workaround: None

VLAN traffic might fail after a NIC reset

A NIC with PCI device ID 8086:1537 might stop to send and receive VLAN tagged packets after a reset, for example, with a command `vsish -e set /net/pNics/vmnic0/reset 1`.

Workaround: Avoid resetting the NIC. If you already face the issue, use the following commands to restore the VLAN capability, for example at vmnic0:

```
# esxcli network nic software set --tagging=1 -n vmnic0# esxcli network nic software set --tagging=0 -n vmnic0
```

Any change in the NetQueue balancer settings causes NetQueue to be disabled after an ESXi host reboot

Any change in the NetQueue balancer settings by using the command `esxcli/localcli network nic queue loadbalancer set -n <nicname> --<lb_setting>` causes NetQueue, which is enabled by default, to be disabled after an ESXi host reboot.

Workaround: After a change in the NetQueue balancer settings and host reboot, use the command `configstorecli config current get -c esx -g network -k nics` to retrieve ConfigStore data to verify whether the `/esx/network/nics/net_queue/load_balancer/enable` is working as expected.

After you run the command, you see output similar to:

```
{"mac": "02:00:0e:6d:14:3e","name": "vmnic1","net_queue": { "load_balancer": { "dynamic_pool": true, "enable": true }},"virtual_mac": "00:50:56:5a:21:11"}
```

If the output is not as expected, for example `"load_balancer": "enable": false"`, run the following command:

```
esxcli/localcli network nic queue loadbalancer state set -n <nicname> -e true
```

Paravirtual RDMA (PVRDMA) network adapters do not support NSX networking policies

If you configure an NSX distributed virtual port for use in PVRDMA traffic, the RDMA protocol traffic over the PVRDMA network adapters does not comply with the NSX network policies.

Workaround: Do not configure NSX distributed virtual ports for use in PVRDMA traffic.

Rollback from converged vSphere Distributed Switch (VDS) to NSX-T VDS is not supported in vSphere 7.0 Update 3

Rollback from converged VDS that supports both vSphere 7 traffic and NSX-T 3 traffic on the same VDS to one N-VDS for NSX-T traffic is not supported in vSphere 7.0 Update 3.

Workaround: None

If you do not set the nmlx5 network driver module parameter, network connectivity or ESXi hosts might fail

If you do not set the `supported_num_ports` module parameter for the `nmlx5_core` driver on an ESXi host with multiple network adapters of versions Mellanox ConnectX-4, Mellanox ConnectX-5 and Mellanox ConnectX-6, the driver might not allocate sufficient memory for operating all the NIC ports for the host. As a result, you might experience network loss or ESXi host failure with purple diagnostic screen, or both.

Workaround: Set the `supported_num_ports` module parameter value in the `nmlx5_core` network driver equal to the total number of Mellanox ConnectX-4, Mellanox ConnectX-5 and Mellanox ConnectX-6 network adapter ports on the ESXi host.

High throughput virtual machines may experience degradation in network performance when Network I/O Control (NetIOC) is enabled

Virtual machines requiring high network throughput can experience throughput degradation when upgrading from vSphere 6.7 to vSphere 7.0 with NetIOC enabled.

Workaround: Adjust the `ethernetx.ctxPerDev` setting to enable multiple worlds.

IPv6 traffic fails to pass through VMkernel ports using IPsec

When you migrate VMkernel ports from one port group to another, IPv6 traffic does not pass through VMkernel ports using IPsec.

Workaround: Remove the IPsec security association (SA) from the affected server, and then reapply the SA. To learn how to set and remove an IPsec SA, see the *vSphere Security* documentation.

Higher ESX network performance with a portion of CPU usage increase

ESX network performance may increase with a portion of CPU usage.

Workaround: Remove and add the network interface with only 1 rx dispatch queue. For example:

```
esxcli network ip interface remove --interface-name=vmk1
esxcli network ip interface add --interface-name=vmk1 --num-rxqueue=1
```

VM might lose Ethernet traffic after hot-add, hot-remove or storage vMotion

A VM might stop receiving Ethernet traffic after a hot-add, hot-remove or storage vMotion. This issue affects VMs where the uplink of the VNIC has SR-IOV enabled. PVRDMA virtual NIC exhibits this issue when the uplink of the virtual network is a Mellanox RDMA capable NIC and RDMA namespaces are configured.

Workaround: You can hot-remove and hot-add the affected Ethernet NICs of the VM to restore traffic. On Linux guest operating systems, restarting the network might also resolve the issue. If these workarounds have no effect, you can reboot the VM to restore network connectivity.

Change of IP address for a VCSA deployed with static IP address requires that you create the DNS records in advance

With the introduction of the DDNS, the DNS record update only works for VCSA deployed with DHCP configured networking. While changing the IP address of the vCenter server via VAMI, the following error is displayed:

The specified IP address does not resolve to the specified hostname.

Workaround: There are two possible workarounds.

1. Create an additional DNS entry with the same FQDN and desired IP address. Log in to the VAMI and follow the steps to change the IP address.
2. Log in to the VCSA using ssh. Execute the following script:
   `./opt/vmware/share/vami/vami_config_net`
   Use option 6 to change the IP adddress of eth0. Once changed, execute the following script:
   `./opt/likewise/bin/lw-update-dns`
   Restart all the services on the VCSA to update the IP information on the DNS server.

It may take several seconds for the NSX Distributed Virtual Port Group (NSX DVPG) to be removed after deleting the corresponding logical switch in NSX Manager.

As the number of logical switches increases, it may take more time for the NSX DVPG in vCenter Server to be removed after deleting the corresponding logical switch in NSX Manager. In an environment with 12000 logical switches, it takes approximately 10 seconds for an NSX DVPG to be deleted from vCenter Server.

Workaround: None.

Hostd runs out of memory and fails if a large number of NSX Distributed Virtual port groups are created.

In vSphere 7.0, NSX Distributed Virtual port groups consume significantly larger amounts of memory than opaque networks. For this reason, NSX Distributed Virtual port groups can not support the same scale as an opaque network given the same amount of memory.

Workaround:To support the use of NSX Distributed Virtual port groups, increase the amount of memory in your ESXi hosts. If you verify that your system has adequate memory to support your VMs, you can directly increase the memory of `hostd` using the following command.

```
localcli --plugin-dir /usr/lib/vmware/esxcli/int/ sched group setmemconfig --group-path
host/vim/vmvisor/hostd --units mb --min 2048 --max 2048
```

Note that this will cause `hostd` to use memory normally reserved for your environment's VMs. This may have the affect of reducing the number of VMs your ESXi host can support.

DRS may incorrectly launch vMotion if the network reservation is configured on a VM

If the network reservation is configured on a VM, it is expected that DRS only migrates the VM to a host that meets the specified requirements. In a cluster with NSX transport nodes, if some of the transport nodes join the transport zone by NSX-T Virtual Distributed Switch (N-VDS), and others by vSphere Distributed Switch (VDS) 7.0, DRS may incorrectly launch vMotion. You might encounter this issue when:

- The VM connects to an NSX logical switch configured with a network reservation.
- Some transport nodes join transport zone using N-VDS, and others by VDS 7.0, or, transport nodes join the transport zone through different VDS 7.0 instances.

Workaround: Make all transport nodes join the transport zone by N-VDS or the same VDS 7.0 instance.

When adding a VMkernel NIC (vmknic) to an NSX portgroup, vCenter Server reports the error "Connecting VMKernel adapter to a NSX Portgroup on a Stateless host is not a supported operation. Please use Distributed Port Group instead."

- For stateless ESXi on Distributed Virtual Switch (VDS), the vmknic on a NSX port group is blocked. You must instead use a Distributed Port Group.
- For stateful ESXi on VDS, vmknic on NSX port group is supported, but vSAN may have an issue if it is using vmknic on a NSX port group.

Workaround: Use a Distributed Port Group on the same VDS.

Enabling SRIOV from vCenter for QLogic 4x10GE QL41164HFCU CNA might fail

If you navigate to the **Edit Settings** dialog for physical network adapters and attempt to enable SR-IOV, the operation might fail when using QLogic 4x10GE QL41164HFCU CNA. Attempting to enable SR-IOV might lead to a network outage of the ESXi host.

Workaround: Use the following command on the ESXi host to enable SRIOV:

```
esxcfg-module
```

vCenter Server fails if the hosts in a cluster using Distributed Resource Scheduler (DRS) join NSX-T networking by a different Virtual Distributed Switch (VDS) or combination of NSX-T Virtual Distributed Switch (NVDS) and VDS

In vSphere 7.0, when using NSX-T networking on vSphere VDS with a DRS cluster, if the hosts do not join the NSX transport zone by the same VDS or NVDS, it can cause vCenter Server to fail.

Workaround: Have hosts in a DRS cluster join the NSX transport zone using the same VDS or NVDS.

Storage Issues

VMFS datastores are not mounted automatically after disk hot remove and hot insert on HPE Gen10 servers with SmartPQI controllers

When SATA disks on HPE Gen10 servers with SmartPQI controllers without expanders are hot removed and hot inserted back to a different disk bay of the same machine, or when multiple disks are hot removed and hot inserted back in a different order, sometimes a new local name is assigned to the disk. The VMFS datastore on that disk appears as a snapshot and will not be mounted back automatically because the device name has changed.

Workaround: None. SmartPQI controller does not support unordered hot remove and hot insert operations.

VOMA check on NVMe based VMFS datastores fails with error

VOMA check is not supported for NVMe based VMFS datastores and will fail with the error:

```
ERROR: Failed to reserve device. Function not implemented
```

Example:

```
# voma -m vmfs -f check -d /vmfs/devices/disks/: <partition#>
Running VMFS Checker version 2.1 in check mode
Initializing LVM metadata, Basic Checks will be done

Checking for filesystem activity
Performing filesystem liveness check..|Scanning for VMFS-6 host activity (4096 bytes/HB, 1024 HBs).
ERROR: Failed to reserve device. Function not implemented
Aborting VMFS volume check
VOMA failed to check device : General Error
```

Workaround: None. If you need to analyse VMFS metadata, collect it using the `-l` option, and pass to VMware customer support. The command for collecting the dump is:

```
voma -l -f dump -d /vmfs/devices/disks/:<partition#>
```

Using the VM reconfigure API to attach an encrypted First Class Disk to an encrypted virtual machine might fail with error

If an FCD and a VM are encrypted with different crypto keys, your attempts to attach the encrypted FCD to the encrypted VM using the `VM reconfigure API` might fail with the error message:

```
Cannot decrypt disk because key or password is incorrect.
```

Workaround: Use the `attachDisk API` rather than the `VM reconfigure API` to attach an encrypted FCD to an encrypted VM.

ESXi host might get in non responding state if a non-head extent of its spanned VMFS datastore enters the Permanent Device Loss (PDL) state

This problem does not occur when a non-head extent of the spanned VMFS datastore fails along with the head extent. In this case, the entire datastore becomes inaccessible and no longer allows I/Os.

In contrast, when only a non-head extent fails, but the head extent remains accessible, the datastore heartbeat appears to be normal. And the I/Os between the host and the datastore continue. However, any I/Os that depend on the failed non-head extent start failing as well. Other I/O transactions might accumulate while waiting for the failing I/Os to resolve, and cause the host to enter the non responding state.

Workaround: Fix the PDL condition of the non-head extent to resolve this issue.

Virtual NVMe Controller is the default disk controller for Windows 10 guest operating systems

The Virtual NVMe Controller is the default disk controller for the following guest operating systems when using Hardware Version 15 or later:

Windows 10

Windows Server 2016

Windows Server 2019

Some features might not be available when using a Virtual NVMe Controller. For more information, see https://kb.vmware.com/s/article/2147714

Note: Some clients use the previous default of LSI Logic SAS. This includes ESXi host client and PowerCLI.

Workaround: If you need features not available on Virtual NVMe, switch to VMware Paravirtual SCSI (PVSCSI) or LSI Logic SAS. For information on using VMware Paravirtual SCSI (PVSCSI), see https://kb.vmware.com/s/article/1010398

After an ESXi host upgrade to vSphere 7.0, presence of duplicate core claim rules might cause unexpected behavior

Claim rules determine which multipathing plugin, such as NMP, HPP, and so on, owns paths to a particular storage device. ESXi 7.0 does not support duplicate claim rules. However, the ESXi 7.0 host does not alert you if you add duplicate rules to the existing claim rules inherited through an upgrade from a legacy release. As a result of using duplicate rules, storage devices might be claimed by unintended plugins, which can cause unexpected outcome.

Workaround: Do not use duplicate core claim rules. Before adding a new claim rule, delete any existing matching claim rule.

A CNS query with the compliance status filter set might take unusually long time to complete

The CNS QueryVolume API enables you to obtain information about the CNS volumes, such as volume health and compliance status. When you check the compliance status of individual volumes, the results are obtained quickly. However, when you invoke the CNS QueryVolume API to check the compliance status of multiple volumes, several tens or hundreds, the query might perform slowly.

Workaround: Avoid using bulk queries. When you need to get compliance status, query one volume at a time or limit the number of volumes in the query API to 20 or fewer. While using the query, avoid running other CNS operations to get the best performance.

A VMFS datastore backed by an NVMe over Fabrics namespace or device might become permanently inaccessible after recovering from an APD or PDL failure

If a VMFS datastore on an ESXi host is backed by an NVMe over Fabrics namespace or device, in case of an all paths down (APD) or permanent device loss (PDL) failure, the datastore might be inaccessible even after recovery. You cannot access the datastore from either the ESXi host or the vCenter Server system.

Workaround: To recover from this state, perform a rescan on a host or cluster level. For more information, see Perform Storage Rescan.

Deleted CNS volumes might temporarily appear as existing in the CNS UI

After you delete an FCD disk that backs a CNS volume, the volume might still show up as existing in the CNS UI. However, your attempts to delete the volume fail. You might see an error message similar to the following:

```
The object or item referred to could not be found.
```

Workaround: The next full synchronization will resolve the inconsistency and correctly update the CNS UI.

Attempts to attach multiple CNS volumes to the same pod might occasionally fail with an error

When you attach multiple volumes to the same pod simultaneously, the attach operation might occasionally choose the same controller slot. As a result, only one of the operations succeeds, while other volume mounts fail.

Workaround: After Kubernetes retries the failed operation, the operation succeeds if a controller slot is available on the node VM.

Under certain circumstances, while a CNS operation fails, the task status appears as successful in the vSphere Client

This might occur when, for example, you use an incompliant storage policy to create a CNS volume. The operation fails, while the vSphere Client shows the task status as successful.

Workaround: The successful task status in the vSphere Client does not guarantee that the CNS operation succeeded. To make sure the operation succeeded, verify its results.

Unsuccessful delete operation for a CNS persistent volume might leave the volume undeleted on the vSphere datastore

This issue might occur when the CNS Delete API attempts to delete a persistent volume that is still attached to a pod. For example, when you delete the Kubernetes namespace where the pod runs. As a result, the volume gets cleared from CNS and the CNS query operation does not return the volume. However, the volume continues to reside on the datastore and cannot be deleted through the repeated CNS Delete API operations.

Workaround: None.

vCenter Server and vSphere Client Issues

Vendor providers go offline after a PNID change

When you change the vCenter IP address (PNID change), the registered vendor providers go offline.

Workaround: Re-register the vendor providers.

Cross vCenter migration of a virtual machine fails with an error

When you use cross vCenter vMotion to move a VM's storage and host to a different vCenter server instance, you might receive the error `The operation is not allowed in the current state.`

This error appears in the UI wizard after the Host Selection step and before the Datastore Selection step, in cases where the VM has an assigned storage policy containing host-based rules such as encryption or any other IO filter rule.

Workaround: Assign the VM and its disks to a storage policy without host-based rules. You might need to decrypt the VM if the source VM is encrypted. Then retry the cross vCenter vMotion action.

Storage Sensors information in Hardware Health tab shows incorrect values on vCenter UI, host UI, and MOB

When you navigate to **Host > Monitor > Hardware Health > Storage Sensors** on vCenter UI, the storage information displays either incorrect or unknown values. The same issue is observed on the host UI and the MOB path `"runtime.hardwareStatusInfo.storageStatusInfo"` as well.

Workaround: None.

vSphere UI host advanced settings shows the current product locker location as empty with an empty default

vSphere UI host advanced settings shows the current product locker location as empty with an empty default. This is inconsistent as the actual product location `symlink` is created and valid. This causes confusion to the user. The default cannot be corrected from UI.

Workaround: User can use the esxcli command on the host to correct the current product locker location default as below.

1. Remove the existing Product Locker Location setting with: `"esxcli system settings advanced remove -o ProductLockerLocation"`

2. Re-add the Product Locker Location setting with the appropriate default:

2.a. If the ESXi is a full installation, the default value is `"/locker/packages/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/locker/packages/vmtoolsRepo"`

2.b. If the ESXi is a PXEboot configuration such as autodeploy, the default value is: `"/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/vmtoolsRepo"`

Run the following command to automatically figure out the location: `export PRODUCT_LOCKER_DEFAULT=`readlink /productLocker``

Add the setting: `esxcli system settings advanced add -d "Path to VMware Tools repository" -o ProductLockerLocation -t string -s $PRODUCT_LOCKER_DEFAULT`

You can combine all the above steps in step 2 by issuing the single command:

```
esxcli system settings advanced add -d "Path to VMware Tools repository" -o
ProductLockerLocation -t string -s `readlink /productLocker`
```

Linked Software-Defined Data Center (SDDC) vCenter Server instances appear in the on-premises vSphere Client if a vCenter Cloud Gateway is linked to the SDDC.

When a vCenter Cloud Gateway is deployed in the same environment as an on-premises vCenter Server, and linked to an SDDC, the SDDC vCenter Server will appear in the on-premises vSphere Client. This is unexpected behavior and the linked SDDC vCenter Server should be ignored. All operations involving the linked SDDC vCenter Server should be performed on the vSphere Client running within the vCenter Cloud Gateway.

Workaround: None.

Virtual Machine Management Issues

UEFI HTTP booting of virtual machines on ESXi hosts of version earlier than 7.0 Update 2 fails

UEFI HTTP booting of virtual machines is supported only on hosts of version ESXi 7.0 Update 2 and later and VMs with HW version 19 or later.

Workaround: Use UEFI HTTP booting only in virtual machines with HW version 19 or later. Using HW version 19 ensures the virtual machines are placed only on hosts with ESXi version 7.0 Update 2 or later.

Virtual machine snapshot operations fail in vSphere Virtual Volumes datastores on Purity version 5.3.10

Virtual machine snapshot operations fail in vSphere Virtual Volumes datastores on Purity version 5.3.10 with an error such as `An error occurred while saving the snapshot: The VVol target encountered a vendor specific error`. The issue is specific for Purity version 5.3.10.

Workaround: Upgrade to Purity version 6.1.7 or follow vendor recommendations.

The postcustomization section of the customization script runs before the guest customization

When you run the guest customization script for a Linux guest operating system, the `precustomization` section of the customization script that is defined in the customization specification runs before the guest customization and the `postcustomization` section runs after that. If you enable Cloud-Init in the guest operating system of a virtual machine, the `postcustomization` section runs before the customization due to a known issue in Cloud-Init.

Workaround: Disable Cloud-Init and use the standard guest customization.

Group migration operations in vSphere vMotion, Storage vMotion, and vMotion without shared storage fail with error

When you perform group migration operations on VMs with multiple disks and multi-level snapshots, the operations might fail with the error `com.vmware.vc.GenericVmConfigFault Failed waiting for data. Error 195887167. Connection closed by remote host, possibly due to timeout.`

Workaround: Retry the migration operation on the failed VMs one at a time.

Deploying an OVF or OVA template from a URL fails with a 403 Forbidden error

The URLs that contain an HTTP query parameter are not supported. For example, `http://webaddress.com?file=abc.ovf` or the Amazon pre-signed S3 URLs.

Workaround: Download the files and deploy them from your local file system.

The third level of nested objects in a virtual machine folder is not visible

Perform the following steps:

1. Navigate to a data center and create a virtual machine folder.
2. In the virtual machine folder, create a nested virtual machine folder.
3. In the second folder, create another nested virtual machine, virtual machine folder, vApp, or VM Template.

As a result, from the VMs and Templates inventory tree you cannot see the objects in the third nested folder.

Workaround: To see the objects in the third nested folder, navigate to the second nested folder and select the VMs tab.

vSphere HA and Fault Tolerance Issues

VMs in a cluster might be orphaned after recovering from storage inaccessibility such as a cluster wide APD

Some VMs might be in orphaned state after cluster wide APD recovers, even if HA and VMCP are enabled on the cluster.

This issue might be encountered when the following conditions occur simultaneously:

- All hosts in the cluster experience APD and do not recover until VMCP timeout is reached.
- HA primary initiates failover due to APD on a host.
- Power on API during HA failover fails due to one of the following:
  - APD across the same host
  - Cascading APD across the entire cluster
  - Storage issues
  - Resource unavailability
- FDM unregistration and VCs steal VM logic might initiate during a window where FDM has not unregistered the failed VM and VC's host synchronization responds that multiple hosts are reporting the same VM. Both FDM and VC unregister the different registered copies of the same VM from different hosts, causing the VM to be orphaned.

Workaround: You must unregister and reregister the orphaned VMs manually within the cluster after the APD recovers.

If you do not manually reregister the orphaned VMs, HA attempts failover of the orphaned VMs, but it might take between 5 to 10 hours depending on when APD recovers.

The overall functionality of the cluster is not affected in these cases and HA will continue to protect the VMs. This is an anomaly in what gets displayed on VC for the duration of the problem.

vSphere Lifecycle Manager Issues

vSphere Lifecycle Manager and vSAN File Services cannot be simultaneously enabled on a vSAN cluster in vSphere 7.0 release

If vSphere Lifecycle Manager is enabled on a cluster, vSAN File Services cannot be enabled on the same cluster and vice versa. In order to enable vSphere Lifecycle Manager on a cluster, which has VSAN File Services enabled already, first disable vSAN File Services and retry the operation. Please note that if you transition to a cluster that is managed by a single image, vSphere Lifecycle Manager cannot be disabled on that cluster.

Workaround: None.

When a hardware support manager is unavailable, vSphere High Availability (HA) functionality is impacted

If hardware support manager is unavailable for a cluster that you manage with a single image, where a firmware and drivers addon is selected and vSphere HA is enabled, the vSphere HA functionality is impacted. You may experience the following errors.

- Configuring vSphere HA on a cluster fails.
- Cannot complete the configuration of the vSphere HA agent on a host: `Applying HA VIBs on the cluster encountered a failure.`
- Remediating vSphere HA fails: `A general system error occurred: Failed to get Effective Component map.`
- Disabling vSphere HA fails: Delete Solution task failed. `A general system error occurred: Cannot find hardware support package from depot or hardware support manager.`

Workaround:

- If the hardware support manager is temporarily unavailable, perform the following steps.

1. Reconnect the hardware support manager to vCenter Server.
2. Select a cluster from the Hosts and Cluster menu.
3. Select the Configure tab.
4. Under Services, click vSphere Availability.
5. Re-enable vSphere HA.

- If the hardware support manager is permanently unavailable, perform the following steps.

1. Remove the hardware support manager and the hardware support package from the image specification
2. Re-enable vSphere HA.
3. Select a cluster from the Hosts and Cluster menu.
4. Select the Updates tab.
5. Click Edit .
6. Remove the firmware and drivers addon and click Save.
7. Select the Configure tab.
8. Under Services, click vSphere Availability.
9. Re-enable vSphere HA.

I/OFilter is not removed from a cluster after a remediation process in vSphere Lifecycle Manager

Removing I/OFilter from a cluster by remediating the cluster in vSphere Lifecycle Manager, fails with the following error message: `iofilter XXX already exists` . The iofilter remains listed as installed.

Workaround:

1. Call IOFilter API `UninstallIoFilter_Task` from the vCenter Server managed object (IoFilterManager).
2. Remediate the cluster in vSphere Lifecycle Manager.
3. Call IOFilter API `ResolveInstallationErrorsOnCluster_Task` from the vCenter Server managed object (IoFilterManager) to update the database.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, adding hosts causes a vSphere HA error state

Adding one or multiple ESXi hosts during a remediation process of a vSphere HA enabled cluster, results in the following error message: `Applying HA VIBs on the cluster encountered a failure.`

Workaround: After the cluster remediation operation has finished, perform one of the following tasks.

- Right-click the failed ESXi host and select *Reconfigure for vSphere HA*.
- Disable and re-enable vSphere HA for the cluster.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, disabling and re-enabling vSphere HA causes a vSphere HA error state

Disabling and re-enabling vSphere HA during remediation process of a cluster, may fail the remediation process due to vSphere HA health checks reporting that hosts don't have vSphere HA VIBs installed. You may see the following error message: `Setting desired image spec for cluster failed.`

Workaround: After the cluster remediation operation has finished, disable and re-enable vSphere HA for the cluster.

Checking for recommended images in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the recommendation generation task could take more than an hour to finish or may appear to hang. The completion time for the recommendation task depends on the number of devices configured on each host and the number of image candidates from the depot that vSphere Lifecycle Manager needs to process before obtaining a valid image to recommend.

Workaround: None.

Checking for hardware compatibility in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the validation report generation task could take up to 30 minutes to finish or may appear to hang. The completion time depends on the number of devices configured on each host and the number of hosts configured in the cluster.

Workaround: None

Incomplete error messages in non-English languages are displayed, when remediating a cluster in vSphere Lifecycle Manager

You can encounter incomplete error messages for localized languages in the vCenter Server user interface. The messages are displayed, after a cluster remediation process in vSphere Lifecycle Manager fails. For example, your can observe the following error message.

The error message in English language: `Virtual machine 'VMC on DELL EMC -FileServer' that runs on cluster 'Cluster-1' reported an issue which prevents entering maintenance mode: Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

The error message in French language: `La VM « VMC on DELL EMC -FileServer », située sur le cluster « {Cluster-1} », a signalé un problème empêchant le passage en mode de maintenance : Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

Workaround: None.

Importing an image with no vendor addon, components, or firmware and drivers addon to a cluster which image contains such elements, does not remove the image elements of the existing image

Only the ESXi base image is replaced with the one from the imported image.

Workaround: After the import process finishes, edit the image, and if needed, remove the vendor addon, components, and firmware and drivers addon.

When you convert a cluster that uses baselines to a cluster that uses a single image, a warning is displayed that vSphere HA VIBs will be removed

Converting a vSphere HA enabled cluster that uses baselines to a cluster that uses a single image, may result a warning message displaying that `vmware-fdm` component will be removed.

Workaround: This message can be ignored. The conversion process installs the `vmware-fdm` component.

If vSphere Update Manager is configured to download patch updates from the Internet through a proxy server, after upgrade to vSphere 7.0 that converts Update Manager to vSphere Lifecycle Manager, downloading patches from VMware patch repository might fail

In earlier releases of vCenter Server you could configure independent proxy settings for vCenter Server and vSphere Update Manager. After an upgrade to vSphere 7.0, vSphere Update Manager service becomes part of the vSphere Lifecycle Manager service. For the vSphere Lifecycle Manager service, the proxy settings are configured from the vCenter Server appliance settings. If you had configured Update Manager to download patch updates from the Internet through a proxy server but the vCenter Server appliance had no proxy setting configuration, after a vCenter Server upgrade to version 7.0, the vSphere Lifecycle Manager fails to connect to the VMware depot and is unable to download patches or updates.

Workaround: Log in to the vCenter Server Appliance Management Interface, https://*vcenter-server-appliance-FQDN-or-IP-address*:5480, to configure proxy settings for the vCenter Server appliance and enable vSphere Lifecycle Manager to use proxy.

Miscellaneous Issues

When applying a host profile with version 6.5 to a ESXi host with version 7.0, the compliance check fails

Applying a host profile with version 6.5 to a ESXi host with version 7.0, results in Coredump file profile reported as not compliant with the host.

Workaround: There are two possible workarounds.

1. When you create a host profile with version 6.5, set an advanced configuration option VMkernel.Boot.autoCreateDumpFile to false on the ESXi host.
2. When you apply an existing host profile with version 6.5, add an advanced configuration option VMkernel.Boot.autoCreateDumpFile in the host profile, configure the option to a fixed policy, and set value to false.

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit minor throughput degradation when Dynamic Receive Side Scaling (DYN_RSS) or Generic RSS (GEN_RSS) feature is turned on

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit less than 5 percent throughput degradation when DYN_RSS and GEN_RSS feature is turned on, which is unlikely to impact normal workloads.

Workaround: You can disable DYN_RSS and GEN_RSS feature with the following commands:

```
# esxcli system module parameters set -m nmlx5_core -p "DYN_RSS=0 GEN_RSS=0"
# reboot
```

RDMA traffic between two VMs on the same host might fail in PVRDMA environment

In a vSphere 7.0 implementation of a PVRDMA environment, VMs pass traffic through the HCA for local communication if an HCA is present. However, loopback of RDMA traffic does not work on qedrntv driver. For instance, RDMA Queue Pairs running on VMs that are configured under same uplink port cannot communicate with each other.

In vSphere 6.7 and earlier, HCA was used for local RDMA traffic if SRQ was enabled. vSphere 7.0 uses HCA loopback with VMs using versions of PVRDMA that have SRQ enabled with a minimum of HW v14 using RoCE v2.

The current version of Marvell FastLinQ adapter firmware does not support loopback traffic between QPs of the same PF or port.

Workaround: Required support is being added in the out-of-box driver certified for vSphere 7.0. If you are using the inbox qedrntv driver, you must use a 3-host configuration and migrate VMs to the third host.

Unreliable Datagram traffic QP limitations in qedrntv driver

There are limitations with the Marvell FastLinQ qedrntv RoCE driver and Unreliable Datagram (UD) traffic. UD applications involving bulk traffic might fail with qedrntv driver. Additionally, UD QPs can only work with DMA Memory Regions (MR). Physical MRs or FRMR are not supported. Applications attempting to use physical MR or FRMR along with UD QP fail to pass traffic when used with qedrntv driver. Known examples of such test applications are `ibv_ud_pingpong` and `ib_send_bw`.

Standard RoCE and RoCEv2 use cases in a VMware ESXi environment such as iSER, NVMe-oF (RoCE) and PVRDMA are not impacted by this issue. Use cases for UD traffic are limited and this issue impacts a small set of applications requiring bulk UD traffic.

Marvell FastLinQ hardware does not support RDMA UD traffic offload. In order to meet the VMware PVRDMA requirement to support GSI QP, a restricted software only implementation of UD QP support was added to the qedrntv driver. The goal of the implementation is to provide support for control path GSI communication and is not a complete implementation of UD QP supporting bulk traffic and advanced features.

Since UD support is implemented in software, the implementation might not keep up with heavy traffic and packets might be dropped. This can result in failures with bulk UD traffic.

Workaround: Bulk UD QP traffic is not supported with qedrntv driver and there is no workaround at this time. VMware ESXi RDMA (RoCE) use cases like iSER, NVMe, RDMA and PVRDMA are unaffected by this issue.

Servers equipped with QLogic 578xx NIC might fail when frequently connecting or disconnecting iSCSI LUNs

If you trigger QLogic 578xx NIC iSCSI connection or disconnection frequently in a short time, the server might fail due to an issue with the qfle3 driver. This is caused by a known defect in the device's firmware.

Workaround: None.

ESXi might fail during driver unload or controller disconnect operation in Broadcom NVMe over FC environment

In Broadcom NVMe over FC environment, ESXi might fail during driver unload or controller disconnect operation and display an error message such as: `@BlueScreen: #PF Exception 14 in world 2098707:vmknvmeGener IP 0x4200225021cc addr 0x19`

Workaround: None.

ESXi does not display OEM firmware version number of i350/X550 NICs on some Dell servers

The inbox ixgben driver only recognizes firmware data version or signature for i350/X550 NICs. On some Dell servers the OEM firmware version number is programmed into the OEM package version region, and the inbox ixgben driver does not read this information. Only the 8-digit firmware signature is displayed.

Workaround: To display the OEM firmware version number, install async ixgben driver version 1.7.15 or later.

X710 or XL710 NICs might fail in ESXi

When you initiate certain destructive operations to X710 or XL710 NICs, such as resetting the NIC or manipulating VMKernel's internal device tree, the NIC hardware might read data from non-packet memory.

Workaround: Do not reset the NIC or manipulate vmkernel internal device state.

NVMe-oF does not guarantee persistent VMHBA name after system reboot

NVMe-oF is a new feature in vSphere 7.0. If your server has a USB storage installation that uses vmhba30+ and also has NVMe over RDMA configuration, the VMHBA name might change after a system reboot. This is because the VMHBA name assignment for NVMe over RDMA is different from PCIe devices. ESXi does not guarantee persistence.

Workaround: None.

Backup fails for vCenter database size of 300 GB or greater

If the vCenter database size is 300 GB or greater, the file-based backup will fail with a timeout. The following error message is displayed: `Timeout! Failed to complete in 72000 seconds`

Workaround: None.

A restore of vCenter Server 7.0 which is upgraded from vCenter Server 6.x with External Platform Services Controller to vCenter Server 7.0 might fail

When you restore a vCenter Server 7.0 which is upgraded from 6.x with External Platform Services Controller to vCenter Server 7.0, the restore might fail and display the following error: `Failed to retrieve appliance storage list`

Workaround: During the first stage of the restore process, increase the storage level of the vCenter Server 7.0. For example if the vCenter Server 6.7 External Platform Services Controller setup storage type is small, select storage type large for the restore process.

Enabled SSL protocols configuration parameter is not configured during a host profile remediation process

`Enabled SSL protocols` configuration parameter is not configured during a host profile remediation and only the system default protocol `tlsv1.2` is enabled. This behavior is observed for a host profile with version 7.0 and earlier in a vCenter Server 7.0 environment.

Workaround: To enable TLSV 1.0 or TLSV 1.1 SSL protocols for SFCB, log in to an ESXi host by using SSH, and run the following ESXCLI command: `esxcli system wbem -P <protocol_name>`

Unable to configure Lockdown Mode settings by using Host Profiles

Lockdown Mode cannot be configured by using a security host profile and cannot be applied to multiple ESXi hosts at once. You must manually configure each host.

Workaround: In vCenter Server 7.0, you can configure Lockdown Mode and manage Lockdown Mode exception user list by using a security host profile.

When a host profile is applied to a cluster, Enhanced vMotion Compatibility (EVC) settings are missing from the ESXi hosts

Some settings in the VMware config file `/etc/vmware/config` are not managed by Host Profiles and are blocked, when the config file is modified. As a result, when the host profile is applied to a cluster, the EVC settings are lost, which causes loss of EVC functionalities. For example, unmasked CPUs can be exposed to workloads.

Workaround: Reconfigure the relevant EVC baseline on cluster to recover the EVC settings.

Using a host profile that defines a core dump partition in vCenter Server 7.0 results in an error

In vCenter Server 7.0, configuring and managing a core dump partition in a host profile is not available. Attempting to apply a host profile that defines a core dump partition, results in the following error: `No valid coredump partition found.`

Workaround: None. In vCenter Server 7.0., Host Profiles supports only file-based core dumps.

If you run the ESXCLI command to unload the firewall module, the hostd service fails and ESXi hosts lose connectivity

If you automate the firewall configuration in an environment that includes multiple ESXi hosts, and run the ESXCLI command `esxcli network firewall unload` that destroys filters and unloads the firewall module, the hostd service fails and ESXi hosts lose connectivity.

Workaround: Unloading the firewall module is not recommended at any time. If you must unload the firewall module, use the following steps:

1. Stop the hostd service by using the command:
   `/etc/init.d/hostd stop.`
2. Unload the firewall module by using the command:
   `esxcli network firewall unload.`
3. Perform the required operations.
4. Load the firewall module by using the command:
   `esxcli network firewall load.`
5. Start the hostd service by using the command:
   `/etc/init.d/hostd start.`

vSphere Storage vMotion operations might fail in a vSAN environment due to an unauthenticated session of the Network File Copy (NFC) manager

Migrations to a vSAN datastore by using vSphere Storage vMotion of virtual machines that have at least one snapshot and more than one virtual disk with different storage policy might fail. The issue occurs due to an unauthenticated session of the NFC manager because the Simple Object Access Protocol (SOAP) body exceeds the allowed size.

Workaround: First migrate the VM home namespace and just one of the virtual disks. After the operation completes, perform a disk only migration of the remaining 2 disks.

Changes in the properties and attributes of the devices and storage on an ESXi host might not persist after a reboot

If the device discovery routine during a reboot of an ESXi host times out, the jumpstart plug-in might not receive all configuration changes of the devices and storage from all the registered devices on the host. As a result, the process might restore the properties of some devices or storage to the default values after the reboot.

Workaround: Manually restore the changes in the properties of the affected device or storage.

If you use a beta build of ESXi 7.0, ESXi hosts might fail with a purple diagnostic screen during some lifecycle operations

If you use a beta build of ESXi 7.0, ESXi hosts might fail with a purple diagnostic screen during some lifecycle operations such as unloading a driver or switching between ENS mode and native driver mode. For example, if you try to change the ENS mode, in the backtrace you see an error message similar to: `case ENS::INTERRUPT::NoVM_DeviceStateWithGracefulRemove hit BlueScreen: ASSERT bora/vmkernel/main/dlmalloc.c:2733` This issue is specific for beta builds and does not affect release builds such as ESXi 7.0.

Workaround: Update to ESXi 7.0 GA.

You cannot create snapshots of virtual machines due to an error that a digest operation has failed

A rare race condition when an All-Paths-Down (APD) state occurs during the update of the Content Based Read Cache (CBRC) digest file might cause inconsistencies in the digest file. As a result, you cannot create virtual machine snapshots. You see an error such as `An error occurred while saving the snapshot: A digest operation has failed` in the backtrace.

Workaround: Power cycle the virtual machines to trigger a recompute of the CBRC hashes and clear the inconsistencies in the digest file.

If you upgrade your ESXi hosts to version 7.0 Update 3, but your vCenter Server is of an earlier version, Trusted Platform Module (TPM) attestation of the ESXi hosts fails

If you upgrade your ESXi hosts to version 7.0 Update 3, but your vCenter Server is of an earlier version, and you enable TPM, ESXi hosts fail to pass attestation. In the vSphere Client, you see the warning Host TPM attestation alarm. The Elliptic Curve Digital Signature Algorithm (ECDSA) introduced with ESXi 7.0 Update 3 causes the issue when vCenter Server is not of version 7.0 Update 3.

Workaround: Upgrade your vCenter Server to 7.0 Update 3 or acknowledge the alarm.

You see warnings in the boot loader screen about TPM asset tags

If a TPM-enabled ESXi host has no asset tag set on, you might see idle warning messages in the boot loader screen such as:

```
Failed to determine TPM asset tag size: Buffer too smallFailed to measure asset tag into TPM: Buffer too small
```

Workaround: Ignore the warnings or set an asset tag by using the command `$ esxcli hardware tpm tag set -d`

The sensord daemon fails to report ESXi host hardware status

A logic error in the IPMI SDR validation might cause `sensord` to fail to identify a source for power supply information. As a result, when you run the command `vsish -e get /power/hostStats`, you might not see any output.

Workaround: None

If an ESXi host fails with a purple diagnostic screen, the netdump service might stop working

In rare cases, if an ESXi host fails with a purple diagnostic screen, the netdump service might fail with an error such as `NetDump FAILED: Couldn't attach to dump server at IP x.x.x.x.`

Workaround: Configure the VMkernel core dump to use local storage.

You see frequent VMware Fault Domain Manager (FDM) core dumps on multiple ESXi hosts

In some environments, the number of datastores might exceed the FDM file descriptor limit. As a result, you see frequent core dumps on multiple ESXi hosts indicating FDM failure.

Workaround: Increase the FDM file descriptor limit to 2048. You can use the setting `das.config.fdm.maxFds` from the vSphere HA advanced options in the vSphere Client. For more information, see Set Advanced Options.

Virtual machines on a vSAN cluster with enabled NSX-T and a converged vSphere Distributed Switch (CVDS) in a VLAN transport zone cannot power on after a power off

If a secondary site is 95% disk full and VMs are powered off before simulating a secondary site failure, during recovery some of the virtual machines fail to power on. As a result, virtual machines become unresponsive. The issue occurs regardless if site recovery includes adding disks or ESXi hosts or CPU capacity.

Workaround: Select the virtual machines that do not power on and change the network to VM Network from Edit Settings on the VM context menu.

ESXI hosts might fail with a purple diagnostic screen with an error Assert at bora/modules/vmkernel/vmfs/fs6Journal.c:835

In rare cases, for example when running SESparse tests, the number of locks per transaction in a VMFS datastore might exceed the limit of 50 for the `J6_MAX_TXN_LOCKACTIONS` parameter. As a result, ESXi hosts might fail with a purple diagnostic screen with an error `Assert at bora/modules/vmkernel/vmfs/fs6Journal.c:835`.

Workaround: None

If you modify the netq_rss_ens parameter of the nmlx5_core driver, ESXi hosts might fail with a purple diagnostic screen

If you try to enable the `netq_rss_ens` parameter when you configure an enhanced data path on the `nmlx5_core` driver, ESXi hosts might fail with a purple diagnostic screen. The `netq_rss_ens` parameter, which enables NetQ RSS, is disabled by default with a value of `0`.

Workaround: Keep the default value for the `netq_rss_ens` module parameter in the `nmlx5_core` driver.

ESXi might terminate I/O to NVMeOF devices due to errors on all active paths

Occasionally, all active paths to NVMeOF device register I/O errors due to link issues or controller state. If the status of one of the paths changes to Dead, the High Performance Plug-in (HPP) might not select another path if it shows high volume of errors. As a result, the I/O fails.

Workaround: Disable the configuration option **/Misc/HppManageDegradedPaths** to unblock the I/O.

Upgrade to ESXi 7.0 Update 3 might fail due to changed name of the inbox i40enu network driver

Starting with vSphere 7.0 Update 3, the inbox i40enu network driver for ESXi changes name back to i40en. The i40en driver was renamed to i40enu in vSphere 7.0 Update 2, but the name change impacted some upgrade paths. For

example, rollup upgrade of ESXi hosts that you manage with baselines and baseline groups from 7.0 Update 2 or 7.0 Update 2a to 7.0 Update 3 fails. In most cases, the i40enu driver upgrades to ESXi 7.0 Update 3 without any additional steps. However, if the driver upgrade fails, you cannot update ESXi hosts that you manage with baselines and baseline groups. You also cannot use host seeding or a vSphere Lifecycle Manager single image to manage the ESXi hosts. If you have already made changes related to the i40enu driver and devices in your system, before upgrading to ESXi 7.0 Update 3, you must uninstall the i40enu VIB or Component on ESXi, or first upgrade ESXi to ESXi 7.0 Update 2c.

Workaround: For more information, see VMware knowledge base article 85982.

SSH access fails after you upgrade to ESXi 7.0 Update 3d

After you upgrade to ESXi 7.0 Update 3d, SSH access might fail in certain conditions due to an update of OpenSSH to version 8.8.

Workaround: For more information, see VMware knowledge base article 88055.

USB device passthrough from ESXi hosts to virtual machines might fail

A USB modem device might simultaneously claim multiple interfaces by the VMkernel and block the device passthrough to VMs.

Workaround: You must apply the USB.quirks advanced configuration on the ESXi host to ignore the NET interface from VMkernel and allow the USB modem to passthrough to VMs. You can apply the configuration in 3 alternative ways:

1. Access the ESXi shell and run the following command: `esxcli system settings advanced set -o /USB/quirks -s 0xvvvv:0xpppp:0:0xffff:UQ_NET_IGNORE | |- Device Product ID |------- Device Vendor ID`
   For example, for the Gemalto M2M GmbH Zoom 4625 Modem(`vid:pid/1e2d:005b`), you can have the command `esxcli system settings advanced set` **-o** `/USB/quirks -s 0x1e2d:0x005b:0:0xffff:UQ_NET_IGNORE`
   Reboot the ESXi host.
2. Set the advanced configuration from the vSphere Client or the vSphere Web Client and reboot the ESXi host.
3. Use a Host Profile to apply the advanced configuration.

For more information on the steps, see VMware knowledge base article 80416.

HTTP requests from certain libraries to vSphere might be rejected

The HTTP reverse proxy in vSphere 7.0 enforces stricter standard compliance than in previous releases. This might expose pre-existing problems in some third-party libraries used by applications for SOAP calls to vSphere.

If you develop vSphere applications that use such libraries or include applications that rely on such libraries in your vSphere stack, you might experience connection issues when these libraries send HTTP requests to VMOMI. For example, HTTP requests issued from vijava libraries can take the following form:

```
POST /sdk HTTP/1.1
SOAPAction
Content-Type: text/xml; charset=utf-8
User-Agent: Java/1.8.0_221
```

The syntax in this example violates an HTTP protocol header field requirement that mandates a colon after SOAPAction. Hence, the request is rejected in flight.

Workaround: Developers leveraging noncompliant libraries in their applications can consider using a library that follows HTTP standards instead. For example, developers who use the vijava library can consider using the latest version of the yavijava library instead.

You might see a dump file when using Broadcom driver lsi_msgpt3, lsi_msgpt35 and lsi_mr3

When using the lsi_msgpt3, lsi_msgpt35 and lsi_mr3 controllers, there is a potential risk to see dump file lsuv2-lsi-drivers-plugin-util-zdump. There is an issue when exiting the storelib used in this plugin utility. There is no impact on ESXi operations, you can ignore the dump file.

Workaround: You can safely ignore this message. You can remove the lsuv2-lsi-drivers-plugin with the following command:

```
esxcli software vib remove -n lsuv2-lsiv2-drivers-plugin
```

You might see reboot is not required after configuring SR-IOV of a PCI device in vCenter, but device configurations made by third party extensions might be lost and require reboot to be re-applied.

In ESXi 7.0, SR-IOV configuration is applied without a reboot and the device driver is reloaded. ESXi hosts might have third party extensions perform device configurations that need to run after the device driver is loaded during boot. A reboot is required for those third party extensions to re-apply the device configuration.

Workaround: You must reboot after configuring SR-IOV to apply third party device configurations.

vSphere Client Issues

BIOS manufacturer displays as "--" in the vSphere Client

In the vSphere Client, when you select an ESXi host and navigate to **Configure** > **Hardware** > **Firmware**, you see `--` instead of the BIOS manufacturer name.

Workaround: For more information, see VMware knowledge base article 88937.

vSAN Issues

PR 2962316: vSAN File Service does not support NFSv4 delegations

vSAN File Service does not support NFSv4 delegations in this release.

Workaround: None

PR 3235496: Applications on a vSAN cluster become intermittently unresponsive

If the advanced option `preferHT` is enabled on an AMD server in a vSAN cluster, the virtual CPUs of a virtual machine run on the same last level cache. When the virtual CPUs are all very busy and an NVMe thread to handle I/Os happens to run also on the same last level cache, the NVMe thread takes very long to complete, because it competes for CPU resources with the busy VMs. As a result, the I/O latency is very high and might lead to intermittent unresponsiveness of storage and applications on the vSAN cluster. In the backlog, you see errors such as `Lost access to volume <uuid> due to connectivity issues. Recovery attempt is in progress and outcome will be reported shortly.`

Workaround: Use the command `esxcli system settings advanced set -o /Misc/vmknvmeCwYield -I 0` to avoid competition between the NVMe completion queue and busy virtual CPUs.

VMware ESXi 7.0 Update 3s Release Notes

This document contains the following sections

- Introduction
- What's New
- Patches Contained in This Release
- Patch Download and Installation

- Resolved Issues
- Known Issues from Previous Releases

Introduction

VMware ESXi 7.0 Update 3s |04 MAR 2025 | Build 24585291 Check for additions and updates to these release notes.

IMPORTANT: If your source system contains hosts of versions between ESXi 7.0 Update 2 and Update 3c, and Intel drivers, before upgrading to ESXi 7.0 Update 3s, see the What's New section of the VMware vCenter Server 7.0 Update 3c Release Notes, because all content in the section is also applicable for vSphere 7.0 Update 3s. Also, see the related VMware knowledge base articles: 86447, 87258, and 87308.

What's New

- This release resolves CVE-2025-22224, CVE-2025-22225, and CVE-2025-22226. For more information on these vulnerabilities and their impact on Broadcom products, see VMSA-2025-0004.

Patches Contained in This Release

This release of ESXi 7.0 Update 3s delivers the following patches:

Build Details

Download Filename:	VMware-ESXi-7.0U3s-24585291-depot.zip
Build:	24585291
Download Size:	382.1 MB
md5sum:	6535f6f9a016fb1a76d6caa086f48891
sha256checksum:	b4de8b0b2b0bf9851dcef9f30cb19ff487b03d8494693acec216eb9635f4dd59
Host Reboot Required:	Yes
Virtual Machine Migration or Shutdown Required:	Yes

Components

Component	Bulletin	Category	Severity
ESXi Component - core ESXi VIBs	ESXi_7.0.3-0.135.24585291	Security	Critical
ESXi Install/Upgrade Component	esx-update_7.0.3-0.135.24585291	Security	Critical

IMPORTANT:

- Starting with vSphere 7.0, VMware uses components for packaging VIBs along with bulletins. The `ESXi` and `esx-update` bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.
- When patching ESXi hosts by using VMware Update Manager from a version prior to ESXi 7.0 Update 2, it is strongly recommended to use the rollup bulletin in the patch baseline. If you cannot use the rollup bulletin, be sure to include

all of the following packages in the patching baseline. If the following packages are not included in the baseline, the update operation fails:

- VMware-vmkusb_0.1-1vmw.701.0.0.16850804 or higher
- VMware-vmkata_0.1-1vmw.701.0.0.16850804 or higher
- VMware-vmkfcoe_1.0.0.2-1vmw.701.0.0.16850804 or higher
- VMware-NVMeoF-RDMA_1.0.1.2-1vmw.701.0.0.16850804 or higher

Rollup Bulletin

This rollup bulletin contains the latest VIBs with all the fixes after the initial release of ESXi 7.0.

Bulletin ID	Category	Severity	Details
ESXi70U3s-24585291	Security	Critical	Security only

Image Profiles

VMware patch and update releases contain general and critical image profiles. Application of the general release image profile applies to new bug fixes.

Image Profile Name
ESXi-7.0U3s-24585291-standard
ESXi-7.0U3s-24585291-no-tools

ESXi Image

Name and Version	Release Date	Category	Details
ESXi7.0U3s - 24585291	March 04 2025	Security	Security only image

Patch Download and Installation

Log in to the Broadcom Support Portal to download this patch.

For download instructions for earlier releases, see Download Broadcom products and software.

In vSphere 7.x, the Update Manager plug-in, used for administering vSphere Update Manager, is replaced with the Lifecycle Manager plug-in. Administrative operations for vSphere Update Manager are still available under the Lifecycle Manager plug-in, along with new capabilities for vSphere Lifecycle Manager.

The typical way to apply patches to ESXi 7.x hosts is by using the vSphere Lifecycle Manager. For details, see About vSphere Lifecycle Manager and vSphere Lifecycle Manager Baselines and Images.

You can also update ESXi hosts without using the Lifecycle Manager plug-in, and use an image profile instead. To do this, you must manually download the patch offline bundle ZIP file.

For details, see Upgrading Hosts by Using ESXCLI Commands, and the VMware ESXi Upgrade guide.

Resolved Issues

The resolved issues are grouped as follows:

ESXi_7.0.3-0.135.24585291

Patch Category	Security

Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs Included	• VMware_bootbank_vdfs_7.0.3-0.135.24585291 • VMware_bootbank_cpu-microcode_7.0.3-0.135.24585291 • VMware_bootbank_crx_7.0.3-0.135.24585291 • VMware_bootbank_esx-dvfilter-generic-fastpath_7.0.3-0.135.24585291 • VMware_bootbank_esx-xserver_7.0.3-0.135.24585291 • VMware_bootbank_gc_7.0.3-0.135.24585291 • VMware_bootbank_native-misc-drivers_7.0.3-0.135.24585291 • VMware_bootbank_trx_7.0.3-0.135.24585291 • VMware_bootbank_vsan_7.0.3-0.135.24585291 • VMware_bootbank_esxio-combiner_7.0.3-0.135.24585291 • VMware_bootbank_bmcal_7.0.3-0.135.24585291 • VMware_bootbank_esx-base_7.0.3-0.135.24585291 • VMware_bootbank_vsanhealth_7.0.3-0.135.24585291
PRs Fixed	N/A
CVE numbers	CVE-2025-22224, CVE-2025-22225, CVE-2025-22226

The ESXi and esx-update bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.

This patch updates the `esx-base` VIB. Due to their dependency with the `esx-base` VIB, the following VIBs are updated with build number and patch version changes, but deliver no fixes: `vdfs`, `cpu-microcode`, `crx`, `esx-dvfilter-generic-fastpath`, `esx-xserver`, `gc`, `native-misc-drivers`, `trx`, `vsan`, `esxio-combiner`, `bmcal`, `vsanhealth` , and `esx-base` . This patch resolves the following issue:

This release resolves CVE-2025-22224, CVE-2025-22225, and CVE-2025-22226. For more information on these vulnerabilities and their impact on Broadcom products, see VMSA-2025-0004.

esx-update_7.0.3-0.135.24585291

Patch Category	Security
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_bootbank_loadesx_7.0.3-0.135.24585291 • VMware_bootbank_esx-update_7.0.3-0.135.24585291
PRs Fixed	N/A
CVE numbers	N/A

Due to their dependency on the `esx-base` VIB, the following VIBs are updated with build number and patch version changes, but deliver no fixes: `loadesx` and `esx-update` .

ESXi-7.0U3s-24585291-standard

Profile Name	ESXi-7.0U3s-24585291-standard
Build	For build information, see Patches Contained in This Release.
Vendor	Broadcom
Release Date	March 04, 2025
Acceptance Level	PartnerSupported
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_bootbank_vdfs_7.0.3-0.135.24585291 • VMware_bootbank_cpu-microcode_7.0.3-0.135.24585291 • VMware_bootbank_crx_7.0.3-0.135.24585291 • VMware_bootbank_esx-dvfilter-generic-fastpath_7.0.3-0.135.24585291 • VMware_bootbank_esx-xserver_7.0.3-0.135.24585291 • VMware_bootbank_gc_7.0.3-0.135.24585291 • VMware_bootbank_native-misc-drivers_7.0.3-0.135.24585291 • VMware_bootbank_trx_7.0.3-0.135.24585291 • VMware_bootbank_vsan_7.0.3-0.135.24585291 • VMware_bootbank_esxio-combiner_7.0.3-0.135.24585291 • VMware_bootbank_bmcal_7.0.3-0.135.24585291 • VMware_bootbank_esx-base_7.0.3-0.135.24585291 • VMware_bootbank_vsanhealth_7.0.3-0.135.24585291 • VMware_bootbank_loadesx_7.0.3-0.135.24585291 • VMware_bootbank_esx-update_7.0.3-0.135.24585291
PRs Fixed	N/A
Related CVE numbers	CVE-2025-22224, CVE-2025-22225, CVE-2025-22226

This patch updates the following issue:

This release resolves CVE-2025-22224, CVE-2025-22225, and CVE-2025-22226. For more information on these vulnerabilities and their impact on Broadcom products, see VMSA-2025-0004.

ESXi-7.0U3s-24585291-no-tools

Profile Name	ESXi-7.0U3s-24585291-no-tools
Build	For build information, see Patches Contained in This Release.
Vendor	Broadcom
Release Date	March 04, 2025
Acceptance Level	PartnerSupported

PRs Fixed	N/A
Related CVE numbers	CVE-2025-22224, CVE-2025-22225, CVE-2025-22226

This patch updates the following issue:

This release resolves CVE-2025-22224, CVE-2025-22225, and CVE-2025-22226. For more information on these vulnerabilities and their impact on Broadcom products, see VMSA-2025-0004.

ESXi7.0U3s - 24585291

Name	ESXi
Version	ESXi7.0U3s - 24585291
Release Date	March 04, 2025
Category	Security
Affected Components	• ESXi Component - core ESXi • ESXi Install/Upgrade
PRs Fixed	N/A
Related CVE numbers	CVE-2025-22224, CVE-2025-22225, CVE-2025-22226

This patch resolves the issues listed in ESXi_7.0.3-0.135.24585291.

Known Issues from Previous Releases

vSphere Cluster Services Issues

You see compatibility issues in new vCLS VMs deployed in vSphere 7.0 Update 3 environment

The default name for new vCLS VMs deployed in vSphere 7.0 Update 3 environment uses the pattern vCLS-UUID. vCLS VMs created in earlier vCenter Server versions continue to use the pattern vCLS (n). Since the use of parenthesis () is not supported by many solutions that interoperate with vSphere, you might see compatibility issues.

Workaround: Reconfigure vCLS by using retreat mode after updating to vSphere 7.0 Update 3.

Installation, Upgrade, and Migration Issues

The vCenter Upgrade/Migration pre-checks fail with "Unexpected error 87"

The vCenter Server Upgrade/Migration pre-checks fail when the Security Token Service (STS) certificate does not contain a Subject Alternative Name (SAN) field. This situation occurs when you have replaced the vCenter 5.5 Single Sign-On certificate with a custom certificate that has no SAN field, and you attempt to upgrade to vCenter Server 7.0. The upgrade considers the STS certificate invalid and the pre-checks prevent the upgrade process from continuing.

Workaround: Replace the STS certificate with a valid certificate that contains a SAN field then proceed with the vCenter Server 7.0 Upgrade/Migration.

Corrupted VFAT partitions from a vSphere 6.7 environment might cause upgrades to ESXi 7.x to fail

Due to corrupted VFAT partitions from a vSphere 6.7 environment, repartitioning the boot disks of an ESXi host might fail during an upgrade to ESXi 7.x. As a result, you might see the following errors:

When upgrading to ESXi 7.0 Update 3l, the operation fails with a purple diagnostic screen and/or an error such as:

- `An error occurred while backing up VFAT partition files before re-partitioning: Failed to calculate size for temporary Ramdisk: <error>.`
- `An error occurred while backing up VFAT partition files before re-partitioning: Failed to copy files to Ramdisk: <error>.`
  If you use an ISO installer, you see the errors, but no purple diagnostic screen.

When upgrading to an ESXi 7.x version earlier than 7.0 Update 3l, you might see:

- Logs such as `ramdisk (root) is full` in the `vmkwarning.log` file.
- Unexpected rollback to ESXi 6.5 or 6.7 on reboot.
- The `/bootbank`,`/altbootbank`, and ESX-OSData partitions are not present.

Workaround: You must first remediate the corrupted partitions before completing the upgrade to ESXi 7.x. For more details, see VMware knowledge base article 91136.

Problems upgrading to vSphere 7.0 with pre-existing CIM providers

After upgrade, previously installed 32-bit CIM providers stop working because ESXi requires 64-bit CIM providers. Customers may lose management API functions related to CIMPDK, NDDK (native DDK), HEXDK, VAIODK (IO filters), and see errors related to **uwglibc** dependency.

The syslog reports module missing, "32 bit shared libraries not loaded."

Workaround: There is no workaround. The fix is to download new 64-bit CIM providers from your vendor.

Installation of 7.0 Update 1 drivers on ESXi 7.0 hosts might fail

You cannot install drivers applicable to ESXi 7.0 Update 1 on hosts that run ESXi 7.0 or 7.0b.

The operation fails with an error, such as:

```
VMW_bootbank_qedrntv_3.40.4.0-12vmw.701.0.0.xxxxxxx requires vmkapi_2_7_0_0, but the requirement cannot be satisfied within the ImageProfile. Please refer to the log file for more details.
```

Workaround: Update the ESXi host to 7.0 Update 1. Retry the driver installation.

UEFI booting of ESXi hosts might stop with an error during an update to ESXi 7.0 Update 2 from an earlier version of ESXi 7.0

If you attempt to update your environment to 7.0 Update 2 from an earlier version of ESXi 7.0by using vSphere Lifecycle Manager patch baselines, UEFI booting of ESXi hosts might stop with an error such as:

```
Loading /boot.cfgFailed to load crypto64.efiFatal error: 15 (Not found)
```

Workaround: For more information, see VMware knowledge base articles 83063 and 83107 .

If legacy VIBs are in use on an ESXi host, vSphere Lifecycle Manager cannot extract a desired software specification to seed to a new cluster

With vCenter Server 7.0 Update 2, you can create a new cluster by importing the desired software specification from a single reference host. However, if legacy VIBs are in use on an ESXi host, vSphere Lifecycle Manager cannot extract in the vCenter Server instance where you create the cluster a reference software specification from such a host. In the `/var/log/lifecycle.log` , you see messages such as:

```
020-11-11T06:54:03Z lifecycle: 1000082644: HostSeeding:499
ERROR Extract depot failed: Checksum doesn't match. Calculated
5b404e28e83b1387841bb417da93c8c796ef2497c8af0f79583fd54e789d8826, expected:
0947542e30b794c721e21fb595f1851b247711d0619c55489a6a8cae6675e796 2020-11-11T06:54:04Z
lifecycle: 1000082644: imagemanagerctl:366 ERROR Extract depot failed.
2020-11-11T06:54:04Z lifecycle: 1000082644: imagemanagerctl:145 ERROR [VibChecksumError]
```

Workaround: Follow the steps described in VMware knowledge base article 83042.

You see a short burst of log messages in the syslog.log after every ESXi boot

After updating to ESXi 7.0 Update 2, you might see a short burst of log messages after every ESXi boot.

Such logs do not indicate any issue with ESXi and you can ignore these messages. For example:

```
2021-01-19T22:44:22Z watchdog-vaai-nasd: '/usr/lib/vmware/nfs/bin/vaai-nasd -f'
exited after 0 seconds (quick failure 127) 12021-01-19T22:44:22Z watchdog-vaai-
nasd: Executing '/usr/lib/vmware/nfs/bin/vaai-nasd -f'2021-01-19T22:44:22.990Z
aainasd[1000051135]: Log for VAAI-NAS Daemon for NFS version=1.0 build=build-00000
option=DEBUG2021-01-19T22:44:22.990Z vaainasd[1000051135]: DictionaryLoadFile: No entries
loaded by dictionary.2021-01-19T22:44:22.990Z vaainasd[1000051135]: DictionaryLoad: Cannot
open file "/usr/lib/vmware/config": No such file or directory.2021-01-19T22:44:22.990Z
vaainasd[1000051135]: DictionaryLoad: Cannot open file "//.vmware/config": No such
file or directory.2021-01-19T22:44:22.990Z vaainasd[1000051135]: DictionaryLoad: Cannot
open file "//.vmware/preferences": No such file or directory.2021-01-19T22:44:22.990Z
vaainasd[1000051135]: Switching to VMware syslog extensions2021-01-19T22:44:22.992Z
vaainasd[1000051135]: Loading VAAI-NAS plugin(s).2021-01-19T22:44:22.992Z
vaainasd[1000051135]: DISKLIB-PLUGIN : Not loading plugin /usr/lib/vmware/nas_plugins/
lib64: Not a shared library.
```

Workaround: None

You see warning messages for missing VIBs in vSphere Quick Boot compatibility check reports

After you upgrade to ESXi 7.0 Update 2, if you check vSphere Quick Boot compatibility of your environment by using the `/usr/lib/vmware/loadesx/bin/loadESXCheckCompat.py` command, you might see some warning messages for missing VIBs in the shell. For example:

```
Cannot find VIB(s) ... in the given VIB collection.Ignoring missing reserved VIB(s) ...,
they are removed from reserved VIB IDs.
```

Such warnings do not indicate a compatibility issue.

Workaround: The missing VIB messages can be safely ignored and do not affect the reporting of vSphere Quick Boot compatibility. The final output line of the `loadESXCheckCompat` command unambiguously indicates if the host is compatible.

Auto bootstrapping a cluster that you manage with a vSphere Lifecycle Manager image fails with an error

If you attempt auto bootstrapping a cluster that you manage with a vSphere Lifecycle Manager image to perform a stateful install and overwrite the VMFS partitions, the operation fails with an error. In the support bundle, you see messages such as:

```
2021-02-11T19:37:43Z Host Profiles[265671 opID=MainThread]: ERROR:
EngineModule::ApplyHostConfig. Exception: [Errno 30] Read-only file system
```

Workaround: Follow vendor guidance to clean the VMFS partition in the target host and retry the operation. Alternatively, use an empty disk. For more information on the disk-partitioning utility on ESXi, see VMware knowledge base article 1036609.

Upgrades to ESXi 7.x from 6.5.x and 6.7.0 by using ESXCLI might fail due to a space limitation

Upgrades to ESXi 7.x from 6.5.x and 6.7.0 by using the `esxcli software profile update` or `esxcli software profile install` ESXCLI commands might fail, because the ESXi bootbank might be less than the size of the image profile. In the ESXi Shell or the PowerCLI shell, you see an error such as:

```
[InstallationError]
 The pending transaction requires 244 MB free space, however the maximum supported size is 239 MB.
 Please refer to the log file for more details.
```

The issue also occurs when you attempt an ESXi host upgrade by using the ESXCLI commands `esxcli software vib update` or `esxcli software vib install`.

Workaround: You can perform the upgrade in two steps, by using the `esxcli software profile update` command to update ESXi hosts to ESXi 6.7 Update 1 or later, and then update to 7.0 Update 1c. Alternatively, you can run an upgrade by using an ISO image and the vSphere Lifecycle Manager.

You cannot migrate linked clones across vCenter Servers

If you migrate a linked clone across vCenter Servers, operations such as power on and delete might fail for the source virtual machine with an `Invalid virtual machine state` error.

Workaround: Keep linked clones on the same vCenter Server as the source VM. Alternatively, promote the linked clone to full clone before migration.

Migration across vCenter Servers of virtual machines with many virtual disks and snapshot levels to a datastore on NVMe over TCP storage might fail

Migration across vCenter Servers of virtual machines with more than 180 virtual disks and 32 snapshot levels to a datastore on NVMe over TCP storage might fail. The ESXi host preemptively fails with an error such as `The migration has exceeded the maximum switchover time of 100 second(s)`.

Workaround: None

A virtual machine with enabled Virtual Performance Monitoring Counters (VPMC) might fail to migrate between ESXi hosts

If you try to migrate a virtual machine with enabled VPMC by using vSphere vMotion, the operation might fail if the target host is using some of the counters to compute memory or performance statistics. The operation fails with an error such as `A performance counter used by the guest is not available on the host CPU`.

Workaround: Power off the virtual machine and use cold migration. For more information, see VMware knowledge base article 81191.

If a live VIB install, upgrade, or remove operation immediately precedes an interactive or scripted upgrade to ESXi 7.0 Update 3 by using the installer ISO, the upgrade fails

When a VIB install, upgrade, or remove operation immediately precedes an interactive or scripted upgrade to ESXi 7.0 Update 3 by using the installer ISO, the ConfigStore might not keep some configurations of the upgrade. As a result, ESXi hosts become inaccessible after the upgrade operation, although the upgrade seems successful. To prevent this issue, the ESXi 7.0 Update 3 installer adds a temporary check to block such scenarios. In the ESXi installer console, you see the following error message: `Live VIB installation, upgrade or removal may cause subsequent ESXi upgrade to fail when using the ISO installer.`

Workaround: Use an alternative upgrade method to avoid the issue, such as using ESXCLI or the vSphere Lifecycle Manager.

Smart Card and RSA SecurID authentication might stop working after upgrading to vCenter Server 7.0

If you have configured vCenter Server for either Smart Card or RSA SecurID authentication, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057 before starting the vSphere 7.0 upgrade process. If you do not perform the workaround as described in the KB, you might see the following error messages and Smart Card or RSA SecurID authentication does not work.

"Smart card authentication may stop working. Smart card settings may not be preserved, and smart card authentication may stop working."

or

"RSA SecurID authentication may stop working. RSA SecurID settings may not be preserved, and RSA SecurID authentication may stop working."

Workaround: Before upgrading to vSphere 7.0, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057.

The vlanid property in custom installation scripts might not work

If you use a custom installation script that sets the `vlanid` property to specify a desired VLAN, the property might not take effect on newly installed ESXi hosts. The issue occurs only when a physical NIC is already connected to DHCP when the installation starts. The `vlanid` property works properly when you use a newly connected NIC.

Workaround: Manually set the VLAN from the Direct Console User Interface after you boot the ESXi host. Alternatively, disable the physical NIC and then boot the host.

HPE servers with Trusted Platform Module (TPM) boot, but remote attestation fails

Some HPE servers do not have enough event log space to properly finish TPM remote attestation. As a result, the VMkernel boots, but remote attestation fails due to the truncated log.

Workaround: None.

Upgrading a vCenter Server with an external Platform Services Controller from 6.7u3 to 7.0 fails with VMAFD error

When you upgrade a vCenter Server deployment using an external Platform Services Controller, you converge the Platform Services Controller into a vCenter Server appliance. If the upgrade fails with the error `install.vmafd.vmdir_vdcpromo_error_21`, the VMAFD firstboot process has failed. The VMAFD firstboot process copies the VMware Directory Service Database (data.mdb) from the source Platform Services Controller and replication partner vCenter Server appliance.

Workaround: Disable TCP Segmentation Offload (TSO) and Generic Segmentation Offload (GSO) on the Ethernet adapter of the source Platform Services Controller or replication partner vCenter Server appliance before upgrading a vCenter Server with an external Platform Services Controller. See Knowledge Base article: https://kb.vmware.com/s/article/74678

Smart card and RSA SecurID settings may not be preserved during vCenter Server upgrade

Authentication using RSA SecurID will not work after upgrading to vCenter Server 7.0. An error message will alert you to this issue when attempting to login using your RSA SecurID login.

Workaround: Reconfigure the smart card or RSA SecureID.

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with network error message

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with the error message `IP already exists in the network`. This prevents the migration process from configuring the network parameters on the new vCenter Server appliance. For more information, examine the log file: `/var/log/vmware/upgrade/UpgradeRunner.log`

Workaround:

1. Verify that all Windows Updates have been completed on the source vCenter Server for Windows instance, or disable automatic Windows Updates until after the migration finishes.
2. Retry the migration of vCenter Server for Windows to vCenter Server appliance 7.0.

When you configure the number of virtual functions for an SR-IOV device by using the max_vfs module parameter, the changes might not take effect

In vSphere 7.0, you can configure the number of virtual functions for an SR-IOV device by using the Virtual Infrastructure Management (VIM) API, for example, through the vSphere Client. The task does not require reboot of the ESXi host. After you use the VIM API configuration, if you try to configure the number of SR-IOV virtual functions by using the `max_vfs` module parameter, the changes might not take effect because they are overridden by the VIM API configuration.

Workaround: None. To configure the number of virtual functions for an SR-IOV device, use the same method every time. Use the VIM API or use the `max_vfs` module parameter and reboot the ESXi host.

Upgraded vCenter Server appliance instance does not retain all the secondary networks (NICs) from the source instance

During a major upgrade, if the source instance of the vCenter Server appliance is configured with multiple secondary networks other than the VCHA NIC, the target vCenter Server instance will not retain secondary networks other than the VCHA NIC. If the source instance is configured with multiple NICs that are part of VDS port groups, the NIC configuration will not be preserved during the upgrade. Configurations for vCenter Server appliance instances that are part of the standard port group will be preserved.

Workaround: None. Manually configure the secondary network in the target vCenter Server appliance instance.

After upgrading or migrating a vCenter Server with an external Platform Services Controller, users authenticating using Active Directory lose access to the newly upgraded vCenter Server instance

After upgrading or migrating a vCenter Server with an external Platform Services Controller, if the newly upgraded vCenter Server is not joined to an Active Directory domain, users authenticating using Active Directory will lose access to the vCenter Server instance.

Workaround: Verify that the new vCenter Server instance has been joined to an Active Directory domain. See Knowledge Base article: https://kb.vmware.com/s/article/2118543

Migrating a vCenter Server for Windows with an external Platform Services Controller using an Oracle database fails

If there are non-ASCII strings in the Oracle events and tasks table the migration can fail when exporting events and tasks data. The following error message is provided: UnicodeDecodeError

Workaround: None.

After an ESXi host upgrade, a Host Profile compliance check shows non-compliant status while host remediation tasks fail

The non-compliant status indicates an inconsistency between the profile and the host.

This inconsistency might occur because ESXi 7.0 does not allow duplicate claim rules, but the profile you use contains duplicate rules. For example, if you attempt to use the Host Profile that you extracted from the host before upgrading ESXi 6.5 or ESXi 6.7 to version 7.0 and the Host Profile contains any duplicate claim rules of system default rules, you might experience the problems.

Workaround:

1. Remove any duplicate claim rules of the system default rules from the Host Profile document.
2. Check the compliance status.
3. Remediate the host.
4. If the previous steps do not help, reboot the host.

Error message displays in the vCenter Server Management Interface

After installing or upgrading to vCenter Server 7.0, when you navigate to the Update panel within the vCenter Server Management Interface, the error message "Check the URL and try again" displays. The error message does not prevent you from using the functions within the Update panel, and you can view, stage, and install any available updates.

Workaround: None.

Security Features Issues

Turn off the Service Location Protocol service in ESXi, slpd, to prevent potential security vulnerabilities

Some services in ESXi that run on top of the host operating system, including slpd, the CIM object broker, sfcbd, and the related openwsmand service, have proven security vulnerabilities. VMware has addressed all known vulnerabilities in VMSA-2019-0022 and VMSA-2020-0023, and the fixes are part of the vSphere 7.0 Update 2 release. While sfcbd and openwsmand are disabled by default in ESXi, slpd is enabled by default and you must turn it off, if not necessary, to prevent exposure to a future vulnerability after an upgrade.

Workaround: To turn off the slpd service, run the following PowerCLI commands:

```
$ Get-VMHost | Get-VmHostService | Where-Object {$_.key -eq “slpd”} | Set-VMHostService -policy “off”$ Get-VMHost | Get-VmHostService | Where-Object {$_.key -eq “slpd”} | Stop-VMHostService -Confirm:$false
```

Alternatively, you can use the command `chkconfig slpd off && /etc/init.d/slpd stop`.

The openwsmand service is not on the ESXi services list and you can check the service state by using the following PowerCLI commands:

```
$esx=(Get-EsxCli -vmhost xx.xx.xx.xx -v2)$esx.system.process.list.invoke() | where CommandLine -like '*openwsman*' | select commandline
```

In the ESXi services list, the sfcbd service appears as sfcbd-watchdog.

For more information, see VMware knowledge base articles 76372 and 1025757.

Encrypted virtual machine fails to power on when HA-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled HA on the Trusted Cluster and one or more hosts in the cluster fails attestation, an encrypted virtual machine cannot power on.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Encrypted virtual machine fails to power on when DRS-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled DRS on the Trusted Cluster and one or more hosts in the cluster fails attestation, DRS might try to power on an encrypted virtual machine on an unattested host in the cluster. This operation puts the virtual machine in a locked state.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Migrating or cloning encrypted virtual machines across vCenter Server instances fails when attempting to do so using the vSphere Client

If you try to migrate or clone an encrypted virtual machine across vCenter Server instances using the vSphere Client, the operation fails with the following error message: "The operation is not allowed in the current state."

Workaround: You must use the vSphere APIs to migrate or clone encrypted virtual machines across vCenter Server instances.

Networking Issues

Reduced throughput in networking performance on Intel 82599/X540/X550 NICs

The new queue-pair feature added to ixgben driver to improve networking performance on Intel 82599EB/X540/X550 series NICs might reduce throughput under some workloads in vSphere 7.0 as compared to vSphere 6.7.

Workaround: To achieve the same networking performance as vSphere 6.7, you can disable the queue-pair with a module parameter. To disable the queue-pair, run the command:

```
# esxcli system module parameters set -p "QPair=0,0,0,0..." -m ixgben
```

After running the command, reboot.

One or more I/O devices do not generate interrupts when the AMD IOMMU is in use

If the I/O devices on your ESXi host provide more than a total of 512 distinct interrupt sources, some sources are erroneously assigned an interrupt-remapping table entry (IRTE) index in the AMD IOMMU that is greater than the maximum value. Interrupts from such a source are lost, so the corresponding I/O device behaves as if interrupts are disabled.

Workaround: Use the ESXCLI command `esxcli system settings kernel set -s iovDisableIR -v true` to disable the AMD IOMMU interrupt remapper. Reboot the ESXi host so that the command takes effect.

When you set auto-negotiation on a network adapter, the device might fail

In some environments, if you set link speed to auto-negotiation for network adapters by using the command `esxcli network nic set -a -n vmmicx` , the devices might fail and reboot does not recover connectivity. The issue is specific to a combination of some Intel X710/X722 network adapters, a SFP+ module and a physical switch, where auto-negotiate speed/duplex scenario is not supported.

Workaround: Make sure you use an Intel-branded SFP+ module. Alternatively, use a Direct Attach Copper (DAC) cable.

Solarflare x2542 and x2541 network adapters configured in 1x100G port mode achieve throughput of up to 70Gbps in a vSphere environment

vSphere 7.0 Update 2 supports Solarflare x2542 and x2541 network adapters configured in 1x100G port mode. However, you might see a hardware limitation in the devices that causes the actual throughput to be up to some 70Gbps in a vSphere environment.

Workaround: None

VLAN traffic might fail after a NIC reset

A NIC with PCI device ID 8086:1537 might stop to send and receive VLAN tagged packets after a reset, for example, with a command `vsish -e set /net/pNics/vmnic0/reset 1`.

Workaround: Avoid resetting the NIC. If you already face the issue, use the following commands to restore the VLAN capability, for example at vmnic0:

```
# esxcli network nic software set --tagging=1 -n vmnic0# esxcli network nic software set --tagging=0 -n vmnic0
```

Any change in the NetQueue balancer settings causes NetQueue to be disabled after an ESXi host reboot

Any change in the NetQueue balancer settings by using the command `esxcli/localcli network nic queue loadbalancer set -n <nicname> --<lb_setting>` causes NetQueue, which is enabled by default, to be disabled after an ESXi host reboot.

Workaround: After a change in the NetQueue balancer settings and host reboot, use the command `configstorecli config current get -c esx -g network -k nics` to retrieve ConfigStore data to verify whether the `/esx/network/nics/net_queue/load_balancer/enable` is working as expected.

After you run the command, you see output similar to:

```
{"mac": "02:00:0e:6d:14:3e","name": "vmnic1","net_queue": { "load_balancer": { "dynamic_pool": true, "enable": true }},"virtual_mac": "00:50:56:5a:21:11"}
```

If the output is not as expected, for example `"load_balancer": "enable": false"`, run the following command:

```
esxcli/localcli network nic queue loadbalancer state set -n <nicname> -e true
```

Paravirtual RDMA (PVRDMA) network adapters do not support NSX networking policies

If you configure an NSX distributed virtual port for use in PVRDMA traffic, the RDMA protocol traffic over the PVRDMA network adapters does not comply with the NSX network policies.

Workaround: Do not configure NSX distributed virtual ports for use in PVRDMA traffic.

Rollback from converged vSphere Distributed Switch (VDS) to NSX-T VDS is not supported in vSphere 7.0 Update 3

Rollback from converged VDS that supports both vSphere 7 traffic and NSX-T 3 traffic on the same VDS to one N-VDS for NSX-T traffic is not supported in vSphere 7.0 Update 3.

Workaround: None

If you do not set the nmlx5 network driver module parameter, network connectivity or ESXi hosts might fail

If you do not set the `supported_num_ports` module parameter for the `nmlx5_core` driver on an ESXi host with multiple network adapters of versions Mellanox ConnectX-4, Mellanox ConnectX-5 and Mellanox ConnectX-6, the driver might not allocate sufficient memory for operating all the NIC ports for the host. As a result, you might experience network loss or ESXi host failure with purple diagnostic screen, or both.

Workaround: Set the `supported_num_ports` module parameter value in the `nmlx5_core` network driver equal to the total number of Mellanox ConnectX-4, Mellanox ConnectX-5 and Mellanox ConnectX-6 network adapter ports on the ESXi host.

High throughput virtual machines may experience degradation in network performance when Network I/O Control (NetIOC) is enabled

Virtual machines requiring high network throughput can experience throughput degradation when upgrading from vSphere 6.7 to vSphere 7.0 with NetIOC enabled.

Workaround: Adjust the `ethernetx.ctxPerDev` setting to enable multiple worlds.

IPv6 traffic fails to pass through VMkernel ports using IPsec

When you migrate VMkernel ports from one port group to another, IPv6 traffic does not pass through VMkernel ports using IPsec.

Workaround: Remove the IPsec security association (SA) from the affected server, and then reapply the SA. To learn how to set and remove an IPsec SA, see the *vSphere Security* documentation.

Higher ESX network performance with a portion of CPU usage increase

ESX network performance may increase with a portion of CPU usage.

Workaround: Remove and add the network interface with only 1 rx dispatch queue. For example:

```
esxcli network ip interface remove --interface-name=vmk1
```

```
esxcli network ip interface add --interface-name=vmk1 --num-rxqueue=1
```

VM might lose Ethernet traffic after hot-add, hot-remove or storage vMotion

A VM might stop receiving Ethernet traffic after a hot-add, hot-remove or storage vMotion. This issue affects VMs where the uplink of the VNIC has SR-IOV enabled. PVRDMA virtual NIC exhibits this issue when the uplink of the virtual network is a Mellanox RDMA capable NIC and RDMA namespaces are configured.

Workaround: You can hot-remove and hot-add the affected Ethernet NICs of the VM to restore traffic. On Linux guest operating systems, restarting the network might also resolve the issue. If these workarounds have no effect, you can reboot the VM to restore network connectivity.

Change of IP address for a VCSA deployed with static IP address requires that you create the DNS records in advance

With the introduction of the DDNS, the DNS record update only works for VCSA deployed with DHCP configured networking. While changing the IP address of the vCenter server via VAMI, the following error is displayed:

The specified IP address does not resolve to the specified hostname.

Workaround: There are two possible workarounds.

1. Create an additional DNS entry with the same FQDN and desired IP address. Log in to the VAMI and follow the steps to change the IP address.
2. Log in to the VCSA using ssh. Execute the following script:
   `./opt/vmware/share/vami/vami_config_net`
   Use option 6 to change the IP adddress of eth0. Once changed, execute the following script:
   `./opt/likewise/bin/lw-update-dns`
   Restart all the services on the VCSA to update the IP information on the DNS server.

It may take several seconds for the NSX Distributed Virtual Port Group (NSX DVPG) to be removed after deleting the corresponding logical switch in NSX Manager.

As the number of logical switches increases, it may take more time for the NSX DVPG in vCenter Server to be removed after deleting the corresponding logical switch in NSX Manager. In an environment with 12000 logical switches, it takes approximately 10 seconds for an NSX DVPG to be deleted from vCenter Server.

Workaround: None.

Hostd runs out of memory and fails if a large number of NSX Distributed Virtual port groups are created.

In vSphere 7.0, NSX Distributed Virtual port groups consume significantly larger amounts of memory than opaque networks. For this reason, NSX Distributed Virtual port groups can not support the same scale as an opaque network given the same amount of memory.

Workaround:To support the use of NSX Distributed Virtual port groups, increase the amount of memory in your ESXi hosts. If you verify that your system has adequate memory to support your VMs, you can directly increase the memory of `hostd` using the following command.

```
localcli --plugin-dir /usr/lib/vmware/esxcli/int/ sched group setmemconfig --group-path
host/vim/vmvisor/hostd --units mb --min 2048 --max 2048
```

Note that this will cause `hostd` to use memory normally reserved for your environment's VMs. This may have the affect of reducing the number of VMs your ESXi host can support.

DRS may incorrectly launch vMotion if the network reservation is configured on a VM

If the network reservation is configured on a VM, it is expected that DRS only migrates the VM to a host that meets the specified requirements. In a cluster with NSX transport nodes, if some of the transport nodes join the transport zone by NSX-T Virtual Distributed Switch (N-VDS), and others by vSphere Distributed Switch (VDS) 7.0, DRS may incorrectly launch vMotion. You might encounter this issue when:

- The VM connects to an NSX logical switch configured with a network reservation.
- Some transport nodes join transport zone using N-VDS, and others by VDS 7.0, or, transport nodes join the transport zone through different VDS 7.0 instances.

Workaround: Make all transport nodes join the transport zone by N-VDS or the same VDS 7.0 instance.

When adding a VMkernel NIC (vmknic) to an NSX portgroup, vCenter Server reports the error "Connecting VMKernel adapter to a NSX Portgroup on a Stateless host is not a supported operation. Please use Distributed Port Group instead."

- For stateless ESXi on Distributed Virtual Switch (VDS), the vmknic on a NSX port group is blocked. You must instead use a Distributed Port Group.
- For stateful ESXi on VDS, vmknic on NSX port group is supported, but vSAN may have an issue if it is using vmknic on a NSX port group.

Workaround: Use a Distributed Port Group on the same VDS.

Enabling SRIOV from vCenter for QLogic 4x10GE QL41164HFCU CNA might fail

If you navigate to the **Edit Settings** dialog for physical network adapters and attempt to enable SR-IOV, the operation might fail when using QLogic 4x10GE QL41164HFCU CNA. Attempting to enable SR-IOV might lead to a network outage of the ESXi host.

Workaround: Use the following command on the ESXi host to enable SRIOV:

```
esxcfg-module
```

vCenter Server fails if the hosts in a cluster using Distributed Resource Scheduler (DRS) join NSX-T networking by a different Virtual Distributed Switch (VDS) or combination of NSX-T Virtual Distributed Switch (NVDS) and VDS

In vSphere 7.0, when using NSX-T networking on vSphere VDS with a DRS cluster, if the hosts do not join the NSX transport zone by the same VDS or NVDS, it can cause vCenter Server to fail.

Workaround: Have hosts in a DRS cluster join the NSX transport zone using the same VDS or NVDS.

Storage Issues

VMFS datastores are not mounted automatically after disk hot remove and hot insert on HPE Gen10 servers with SmartPQI controllers

When SATA disks on HPE Gen10 servers with SmartPQI controllers without expanders are hot removed and hot inserted back to a different disk bay of the same machine, or when multiple disks are hot removed and hot inserted back in a different order, sometimes a new local name is assigned to the disk. The VMFS datastore on that disk appears as a snapshot and will not be mounted back automatically because the device name has changed.

Workaround: None. SmartPQI controller does not support unordered hot remove and hot insert operations.

VOMA check on NVMe based VMFS datastores fails with error

VOMA check is not supported for NVMe based VMFS datastores and will fail with the error:

```
ERROR: Failed to reserve device. Function not implemented
```

Example:

```
# voma -m vmfs -f check -d /vmfs/devices/disks/: <partition#>
Running VMFS Checker version 2.1 in check mode
Initializing LVM metadata, Basic Checks will be done

Checking for filesystem activity
Performing filesystem liveness check..|Scanning for VMFS-6 host activity (4096 bytes/HB, 1024 HBs).
ERROR: Failed to reserve device. Function not implemented
Aborting VMFS volume check
VOMA failed to check device : General Error
```

Workaround: None. If you need to analyse VMFS metadata, collect it using the `-l` option, and pass to VMware customer support. The command for collecting the dump is:

```
voma -l -f dump -d /vmfs/devices/disks/:<partition#>
```

Using the VM reconfigure API to attach an encrypted First Class Disk to an encrypted virtual machine might fail with error

If an FCD and a VM are encrypted with different crypto keys, your attempts to attach the encrypted FCD to the encrypted VM using the `VM reconfigure API` might fail with the error message:

```
Cannot decrypt disk because key or password is incorrect.
```

Workaround: Use the `attachDisk API` rather than the `VM reconfigure API` to attach an encrypted FCD to an encrypted VM.

ESXi host might get in non responding state if a non-head extent of its spanned VMFS datastore enters the Permanent Device Loss (PDL) state

This problem does not occur when a non-head extent of the spanned VMFS datastore fails along with the head extent. In this case, the entire datastore becomes inaccessible and no longer allows I/Os.

In contrast, when only a non-head extent fails, but the head extent remains accessible, the datastore heartbeat appears to be normal. And the I/Os between the host and the datastore continue. However, any I/Os that depend on the failed non-head extent start failing as well. Other I/O transactions might accumulate while waiting for the failing I/Os to resolve, and cause the host to enter the non responding state.

Workaround: Fix the PDL condition of the non-head extent to resolve this issue.

Virtual NVMe Controller is the default disk controller for Windows 10 guest operating systems

The Virtual NVMe Controller is the default disk controller for the following guest operating systems when using Hardware Version 15 or later:

Windows 10

Windows Server 2016

Windows Server 2019

Some features might not be available when using a Virtual NVMe Controller. For more information, see https://kb.vmware.com/s/article/2147714

Note: Some clients use the previous default of LSI Logic SAS. This includes ESXi host client and PowerCLI.

Workaround: If you need features not available on Virtual NVMe, switch to VMware Paravirtual SCSI (PVSCSI) or LSI Logic SAS. For information on using VMware Paravirtual SCSI (PVSCSI), see https://kb.vmware.com/s/article/1010398

After an ESXi host upgrade to vSphere 7.0, presence of duplicate core claim rules might cause unexpected behavior

Claim rules determine which multipathing plugin, such as NMP, HPP, and so on, owns paths to a particular storage device. ESXi 7.0 does not support duplicate claim rules. However, the ESXi 7.0 host does not alert you if you add duplicate rules to the existing claim rules inherited through an upgrade from a legacy release. As a result of using duplicate rules, storage devices might be claimed by unintended plugins, which can cause unexpected outcome.

Workaround: Do not use duplicate core claim rules. Before adding a new claim rule, delete any existing matching claim rule.

A CNS query with the compliance status filter set might take unusually long time to complete

The CNS QueryVolume API enables you to obtain information about the CNS volumes, such as volume health and compliance status. When you check the compliance status of individual volumes, the results are obtained quickly. However, when you invoke the CNS QueryVolume API to check the compliance status of multiple volumes, several tens or hundreds, the query might perform slowly.

Workaround: Avoid using bulk queries. When you need to get compliance status, query one volume at a time or limit the number of volumes in the query API to 20 or fewer. While using the query, avoid running other CNS operations to get the best performance.

A VMFS datastore backed by an NVMe over Fabrics namespace or device might become permanently inaccessible after recovering from an APD or PDL failure

If a VMFS datastore on an ESXi host is backed by an NVMe over Fabrics namespace or device, in case of an all paths down (APD) or permanent device loss (PDL) failure, the datastore might be inaccessible even after recovery. You cannot access the datastore from either the ESXi host or the vCenter Server system.

Workaround: To recover from this state, perform a rescan on a host or cluster level. For more information, see Perform Storage Rescan.

Deleted CNS volumes might temporarily appear as existing in the CNS UI

After you delete an FCD disk that backs a CNS volume, the volume might still show up as existing in the CNS UI. However, your attempts to delete the volume fail. You might see an error message similar to the following:

```
The object or item referred to could not be found.
```

Workaround: The next full synchronization will resolve the inconsistency and correctly update the CNS UI.

Attempts to attach multiple CNS volumes to the same pod might occasionally fail with an error

When you attach multiple volumes to the same pod simultaneously, the attach operation might occasionally choose the same controller slot. As a result, only one of the operations succeeds, while other volume mounts fail.

Workaround: After Kubernetes retries the failed operation, the operation succeeds if a controller slot is available on the node VM.

Under certain circumstances, while a CNS operation fails, the task status appears as successful in the vSphere Client

This might occur when, for example, you use an incompliant storage policy to create a CNS volume. The operation fails, while the vSphere Client shows the task status as successful.

Workaround: The successful task status in the vSphere Client does not guarantee that the CNS operation succeeded. To make sure the operation succeeded, verify its results.

Unsuccessful delete operation for a CNS persistent volume might leave the volume undeleted on the vSphere datastore

This issue might occur when the CNS Delete API attempts to delete a persistent volume that is still attached to a pod. For example, when you delete the Kubernetes namespace where the pod runs. As a result, the volume gets cleared from CNS and the CNS query operation does not return the volume. However, the volume continues to reside on the datastore and cannot be deleted through the repeated CNS Delete API operations.

Workaround: None.

vCenter Server and vSphere Client Issues

Vendor providers go offline after a PNID change

When you change the vCenter IP address (PNID change), the registered vendor providers go offline.

Workaround: Re-register the vendor providers.

Cross vCenter migration of a virtual machine fails with an error

When you use cross vCenter vMotion to move a VM's storage and host to a different vCenter server instance, you might receive the error `The operation is not allowed in the current state.`

This error appears in the UI wizard after the Host Selection step and before the Datastore Selection step, in cases where the VM has an assigned storage policy containing host-based rules such as encryption or any other IO filter rule.

Workaround: Assign the VM and its disks to a storage policy without host-based rules. You might need to decrypt the VM if the source VM is encrypted. Then retry the cross vCenter vMotion action.

Storage Sensors information in Hardware Health tab shows incorrect values on vCenter UI, host UI, and MOB

When you navigate to **Host > Monitor > Hardware Health > Storage Sensors** on vCenter UI, the storage information displays either incorrect or unknown values. The same issue is observed on the host UI and the MOB path `"runtime.hardwareStatusInfo.storageStatusInfo"` as well.

Workaround: None.

vSphere UI host advanced settings shows the current product locker location as empty with an empty default

vSphere UI host advanced settings shows the current product locker location as empty with an empty default. This is inconsistent as the actual product location `symlink` is created and valid. This causes confusion to the user. The default cannot be corrected from UI.

Workaround: User can use the esxcli command on the host to correct the current product locker location default as below.

1. Remove the existing Product Locker Location setting with: "`esxcli system settings advanced remove -o ProductLockerLocation`"

2. Re-add the Product Locker Location setting with the appropriate default:

2.a. If the ESXi is a full installation, the default value is "`/locker/packages/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/locker/packages/vmtoolsRepo`"

2.b. If the ESXi is a PXEboot configuration such as autodeploy, the default value is: "`/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/vmtoolsRepo`"

Run the following command to automatically figure out the location: `export PRODUCT_LOCKER_DEFAULT=`readlink /productLocker``

Add the setting: `esxcli system settings advanced add -d "Path to VMware Tools repository" -o ProductLockerLocation -t string -s $PRODUCT_LOCKER_DEFAULT`

You can combine all the above steps in step 2 by issuing the single command:

```
esxcli system settings advanced add -d "Path to VMware Tools repository" -o
ProductLockerLocation -t string -s `readlink /productLocker`
```

Linked Software-Defined Data Center (SDDC) vCenter Server instances appear in the on-premises vSphere Client if a vCenter Cloud Gateway is linked to the SDDC.

When a vCenter Cloud Gateway is deployed in the same environment as an on-premises vCenter Server, and linked to an SDDC, the SDDC vCenter Server will appear in the on-premises vSphere Client. This is unexpected behavior and the linked SDDC vCenter Server should be ignored. All operations involving the linked SDDC vCenter Server should be performed on the vSphere Client running within the vCenter Cloud Gateway.

Workaround: None.

Virtual Machine Management Issues

UEFI HTTP booting of virtual machines on ESXi hosts of version earlier than 7.0 Update 2 fails

UEFI HTTP booting of virtual machines is supported only on hosts of version ESXi 7.0 Update 2 and later and VMs with HW version 19 or later.

Workaround: Use UEFI HTTP booting only in virtual machines with HW version 19 or later. Using HW version 19 ensures the virtual machines are placed only on hosts with ESXi version 7.0 Update 2 or later.

Virtual machine snapshot operations fail in vSphere Virtual Volumes datastores on Purity version 5.3.10

Virtual machine snapshot operations fail in vSphere Virtual Volumes datastores on Purity version 5.3.10 with an error such as `An error occurred while saving the snapshot: The VVol target encountered a vendor specific error`. The issue is specific for Purity version 5.3.10.

Workaround: Upgrade to Purity version 6.1.7 or follow vendor recommendations.

The postcustomization section of the customization script runs before the guest customization

When you run the guest customization script for a Linux guest operating system, the `precustomization` section of the customization script that is defined in the customization specification runs before the guest customization and the `postcustomization` section runs after that. If you enable Cloud-Init in the guest operating system of a virtual machine, the `postcustomization` section runs before the customization due to a known issue in Cloud-Init.

Workaround: Disable Cloud-Init and use the standard guest customization.

Group migration operations in vSphere vMotion, Storage vMotion, and vMotion without shared storage fail with error

When you perform group migration operations on VMs with multiple disks and multi-level snapshots, the operations might fail with the error `com.vmware.vc.GenericVmConfigFault Failed waiting for data. Error 195887167. Connection closed by remote host, possibly due to timeout.`

Workaround: Retry the migration operation on the failed VMs one at a time.

Deploying an OVF or OVA template from a URL fails with a 403 Forbidden error

The URLs that contain an HTTP query parameter are not supported. For example, `http://webaddress.com?file=abc.ovf` or the Amazon pre-signed S3 URLs.

Workaround: Download the files and deploy them from your local file system.

The third level of nested objects in a virtual machine folder is not visible

Perform the following steps:

1. Navigate to a data center and create a virtual machine folder.
2. In the virtual machine folder, create a nested virtual machine folder.
3. In the second folder, create another nested virtual machine, virtual machine folder, vApp, or VM Template.

As a result, from the VMs and Templates inventory tree you cannot see the objects in the third nested folder.

Workaround: To see the objects in the third nested folder, navigate to the second nested folder and select the VMs tab.

vSphere HA and Fault Tolerance Issues

VMs in a cluster might be orphaned after recovering from storage inaccessibility such as a cluster wide APD

Some VMs might be in orphaned state after cluster wide APD recovers, even if HA and VMCP are enabled on the cluster.

This issue might be encountered when the following conditions occur simultaneously:

- All hosts in the cluster experience APD and do not recover until VMCP timeout is reached.
- HA primary initiates failover due to APD on a host.
- Power on API during HA failover fails due to one of the following:
  - APD across the same host
  - Cascading APD across the entire cluster
  - Storage issues
  - Resource unavailability
- FDM unregistration and VCs steal VM logic might initiate during a window where FDM has not unregistered the failed VM and VC's host synchronization responds that multiple hosts are reporting the same VM. Both FDM and VC unregister the different registered copies of the same VM from different hosts, causing the VM to be orphaned.

Workaround: You must unregister and reregister the orphaned VMs manually within the cluster after the APD recovers.

If you do not manually reregister the orphaned VMs, HA attempts failover of the orphaned VMs, but it might take between 5 to 10 hours depending on when APD recovers.

The overall functionality of the cluster is not affected in these cases and HA will continue to protect the VMs. This is an anomaly in what gets displayed on VC for the duration of the problem.

vSphere Lifecycle Manager Issues

vSphere Lifecycle Manager and vSAN File Services cannot be simultaneously enabled on a vSAN cluster in vSphere 7.0 release

If vSphere Lifecycle Manager is enabled on a cluster, vSAN File Services cannot be enabled on the same cluster and vice versa. In order to enable vSphere Lifecycle Manager on a cluster, which has VSAN File Services enabled already, first

disable vSAN File Services and retry the operation. Please note that if you transition to a cluster that is managed by a single image, vSphere Lifecycle Manager cannot be disabled on that cluster.

Workaround: None.

When a hardware support manager is unavailable, vSphere High Availability (HA) functionality is impacted

If hardware support manager is unavailable for a cluster that you manage with a single image, where a firmware and drivers addon is selected and vSphere HA is enabled, the vSphere HA functionality is impacted. You may experience the following errors.

- Configuring vSphere HA on a cluster fails.
- Cannot complete the configuration of the vSphere HA agent on a host: `Applying HA VIBs on the cluster encountered a failure.`
- Remediating vSphere HA fails: `A general system error occurred: Failed to get Effective Component map.`
- Disabling vSphere HA fails: Delete Solution task failed. `A general system error occurred: Cannot find hardware support package from depot or hardware support manager.`

Workaround:

- If the hardware support manager is temporarily unavailable, perform the following steps.

1. Reconnect the hardware support manager to vCenter Server.
2. Select a cluster from the Hosts and Cluster menu.
3. Select the Configure tab.
4. Under Services, click vSphere Availability.
5. Re-enable vSphere HA.

- If the hardware support manager is permanently unavailable, perform the following steps.

1. Remove the hardware support manager and the hardware support package from the image specification
2. Re-enable vSphere HA.
3. Select a cluster from the Hosts and Cluster menu.
4. Select the Updates tab.
5. Click Edit .
6. Remove the firmware and drivers addon and click Save.
7. Select the Configure tab.
8. Under Services, click vSphere Availability.
9. Re-enable vSphere HA.

I/OFilter is not removed from a cluster after a remediation process in vSphere Lifecycle Manager

Removing I/OFilter from a cluster by remediating the cluster in vSphere Lifecycle Manager, fails with the following error message: `iofilter XXX already exists` . The iofilter remains listed as installed.

Workaround:

1. Call IOFilter API `UninstallIoFilter_Task` from the vCenter Server managed object (IoFilterManager).
2. Remediate the cluster in vSphere Lifecycle Manager.
3. Call IOFilter API `ResolveInstallationErrorsOnCluster_Task` from the vCenter Server managed object (IoFilterManager) to update the database.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, adding hosts causes a vSphere HA error state

Adding one or multiple ESXi hosts during a remediation process of a vSphere HA enabled cluster, results in the following error message: `Applying HA VIBs on the cluster encountered a failure.`

Workaround: After the cluster remediation operation has finished, perform one of the following tasks.

- Right-click the failed ESXi host and select *Reconfigure for vSphere HA*.
- Disable and re-enable vSphere HA for the cluster.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, disabling and re-enabling vSphere HA causes a vSphere HA error state

Disabling and re-enabling vSphere HA during remediation process of a cluster, may fail the remediation process due to vSphere HA health checks reporting that hosts don't have vSphere HA VIBs installed. You may see the following error message: `Setting desired image spec for cluster failed.`

Workaround: After the cluster remediation operation has finished, disable and re-enable vSphere HA for the cluster.

Checking for recommended images in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the recommendation generation task could take more than an hour to finish or may appear to hang. The completion time for the recommendation task depends on the number of devices configured on each host and the number of image candidates from the depot that vSphere Lifecycle Manager needs to process before obtaining a valid image to recommend.

Workaround: None.

Checking for hardware compatibility in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the validation report generation task could take up to 30 minutes to finish or may appear to hang. The completion time depends on the number of devices configured on each host and the number of hosts configured in the cluster.

Workaround: None

Incomplete error messages in non-English languages are displayed, when remediating a cluster in vSphere Lifecycle Manager

You can encounter incomplete error messages for localized languages in the vCenter Server user interface. The messages are displayed, after a cluster remediation process in vSphere Lifecycle Manager fails. For example, your can observe the following error message.

The error message in English language: `Virtual machine 'VMC on DELL EMC -FileServer' that runs on cluster 'Cluster-1' reported an issue which prevents entering maintenance mode: Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

The error message in French language: `La VM « VMC on DELL EMC -FileServer », située sur le cluster « {Cluster-1} », a signalé un problème empêchant le passage en mode de maintenance : Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

Workaround: None.

Importing an image with no vendor addon, components, or firmware and drivers addon to a cluster which image contains such elements, does not remove the image elements of the existing image

Only the ESXi base image is replaced with the one from the imported image.

Workaround: After the import process finishes, edit the image, and if needed, remove the vendor addon, components, and firmware and drivers addon.

When you convert a cluster that uses baselines to a cluster that uses a single image, a warning is displayed that vSphere HA VIBs will be removed

Converting a vSphere HA enabled cluster that uses baselines to a cluster that uses a single image, may result a warning message displaying that `vmware-fdm` component will be removed.

Workaround: This message can be ignored. The conversion process installs the `vmware-fdm` component.

If vSphere Update Manager is configured to download patch updates from the Internet through a proxy server, after upgrade to vSphere 7.0 that converts Update Manager to vSphere Lifecycle Manager, downloading patches from VMware patch repository might fail

In earlier releases of vCenter Server you could configure independent proxy settings for vCenter Server and vSphere Update Manager. After an upgrade to vSphere 7.0, vSphere Update Manager service becomes part of the vSphere Lifecycle Manager service. For the vSphere Lifecycle Manager service, the proxy settings are configured from the vCenter Server appliance settings. If you had configured Update Manager to download patch updates from the Internet through a proxy server but the vCenter Server appliance had no proxy setting configuration, after a vCenter Server upgrade to version 7.0, the vSphere Lifecycle Manager fails to connect to the VMware depot and is unable to download patches or updates.

Workaround: Log in to the vCenter Server Appliance Management Interface, https://*vcenter-server-appliance-FQDN-or-IP-address*:5480, to configure proxy settings for the vCenter Server appliance and enable vSphere Lifecycle Manager to use proxy.

Miscellaneous Issues

When applying a host profile with version 6.5 to a ESXi host with version 7.0, the compliance check fails

Applying a host profile with version 6.5 to a ESXi host with version 7.0, results in Coredump file profile reported as not compliant with the host.

Workaround: There are two possible workarounds.

1. When you create a host profile with version 6.5, set an advanced configuration option VMkernel.Boot.autoCreateDumpFile to false on the ESXi host.
2. When you apply an existing host profile with version 6.5, add an advanced configuration option VMkernel.Boot.autoCreateDumpFile in the host profile, configure the option to a fixed policy, and set value to false.

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit minor throughput degradation when Dynamic Receive Side Scaling (DYN_RSS) or Generic RSS (GEN_RSS) feature is turned on

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit less than 5 percent throughput degradation when DYN_RSS and GEN_RSS feature is turned on, which is unlikely to impact normal workloads.

Workaround: You can disable DYN_RSS and GEN_RSS feature with the following commands:

```
# esxcli system module parameters set -m nmlx5_core -p "DYN_RSS=0 GEN_RSS=0"
# reboot
```

RDMA traffic between two VMs on the same host might fail in PVRDMA environment

In a vSphere 7.0 implementation of a PVRDMA environment, VMs pass traffic through the HCA for local communication if an HCA is present. However, loopback of RDMA traffic does not work on qedrntv driver. For instance, RDMA Queue Pairs running on VMs that are configured under same uplink port cannot communicate with each other.

In vSphere 6.7 and earlier, HCA was used for local RDMA traffic if SRQ was enabled. vSphere 7.0 uses HCA loopback with VMs using versions of PVRDMA that have SRQ enabled with a minimum of HW v14 using RoCE v2.

The current version of Marvell FastLinQ adapter firmware does not support loopback traffic between QPs of the same PF or port.

Workaround: Required support is being added in the out-of-box driver certified for vSphere 7.0. If you are using the inbox qedrntv driver, you must use a 3-host configuration and migrate VMs to the third host.

Unreliable Datagram traffic QP limitations in qedrntv driver

There are limitations with the Marvell FastLinQ qedrntv RoCE driver and Unreliable Datagram (UD) traffic. UD applications involving bulk traffic might fail with qedrntv driver. Additionally, UD QPs can only work with DMA Memory Regions (MR). Physical MRs or FRMR are not supported. Applications attempting to use physical MR or FRMR along with UD QP fail to pass traffic when used with qedrntv driver. Known examples of such test applications are `ibv_ud_pingpong` and `ib_send_bw`.

Standard RoCE and RoCEv2 use cases in a VMware ESXi environment such as iSER, NVMe-oF (RoCE) and PVRDMA are not impacted by this issue. Use cases for UD traffic are limited and this issue impacts a small set of applications requiring bulk UD traffic.

Marvell FastLinQ hardware does not support RDMA UD traffic offload. In order to meet the VMware PVRDMA requirement to support GSI QP, a restricted software only implementation of UD QP support was added to the qedrntv driver. The goal of the implementation is to provide support for control path GSI communication and is not a complete implementation of UD QP supporting bulk traffic and advanced features.

Since UD support is implemented in software, the implementation might not keep up with heavy traffic and packets might be dropped. This can result in failures with bulk UD traffic.

Workaround: Bulk UD QP traffic is not supported with qedrntv driver and there is no workaround at this time. VMware ESXi RDMA (RoCE) use cases like iSER, NVMe, RDMA and PVRDMA are unaffected by this issue.

Servers equipped with QLogic 578xx NIC might fail when frequently connecting or disconnecting iSCSI LUNs

If you trigger QLogic 578xx NIC iSCSI connection or disconnection frequently in a short time, the server might fail due to an issue with the qfle3 driver. This is caused by a known defect in the device's firmware.

Workaround: None.

ESXi might fail during driver unload or controller disconnect operation in Broadcom NVMe over FC environment

In Broadcom NVMe over FC environment, ESXi might fail during driver unload or controller disconnect operation and display an error message such as: `@BlueScreen: #PF Exception 14 in world 2098707:vmknvmeGener IP 0x4200225021cc addr 0x19`

Workaround: None.

ESXi does not display OEM firmware version number of i350/X550 NICs on some Dell servers

The inbox ixgben driver only recognizes firmware data version or signature for i350/X550 NICs. On some Dell servers the OEM firmware version number is programmed into the OEM package version region, and the inbox ixgben driver does not read this information. Only the 8-digit firmware signature is displayed.

Workaround: To display the OEM firmware version number, install async ixgben driver version 1.7.15 or later.

X710 or XL710 NICs might fail in ESXi

When you initiate certain destructive operations to X710 or XL710 NICs, such as resetting the NIC or manipulating VMKernel's internal device tree, the NIC hardware might read data from non-packet memory.

Workaround: Do not reset the NIC or manipulate vmkernel internal device state.

NVMe-oF does not guarantee persistent VMHBA name after system reboot

NVMe-oF is a new feature in vSphere 7.0. If your server has a USB storage installation that uses vmhba30+ and also has NVMe over RDMA configuration, the VMHBA name might change after a system reboot. This is because the VMHBA name assignment for NVMe over RDMA is different from PCIe devices. ESXi does not guarantee persistence.

Workaround: None.

Backup fails for vCenter database size of 300 GB or greater

If the vCenter database size is 300 GB or greater, the file-based backup will fail with a timeout. The following error message is displayed: `Timeout! Failed to complete in 72000 seconds`

Workaround: None.

A restore of vCenter Server 7.0 which is upgraded from vCenter Server 6.x with External Platform Services Controller to vCenter Server 7.0 might fail

When you restore a vCenter Server 7.0 which is upgraded from 6.x with External Platform Services Controller to vCenter Server 7.0, the restore might fail and display the following error: `Failed to retrieve appliance storage list`

Workaround: During the first stage of the restore process, increase the storage level of the vCenter Server 7.0. For example if the vCenter Server 6.7 External Platform Services Controller setup storage type is small, select storage type large for the restore process.

Enabled SSL protocols configuration parameter is not configured during a host profile remediation process

`Enabled SSL protocols` configuration parameter is not configured during a host profile remediation and only the system default protocol `tlsv1.2` is enabled. This behavior is observed for a host profile with version 7.0 and earlier in a vCenter Server 7.0 environment.

Workaround: To enable TLSV 1.0 or TLSV 1.1 SSL protocols for SFCB, log in to an ESXi host by using SSH, and run the following ESXCLI command: `esxcli system wbem -P <protocol_name>`

Unable to configure Lockdown Mode settings by using Host Profiles

Lockdown Mode cannot be configured by using a security host profile and cannot be applied to multiple ESXi hosts at once. You must manually configure each host.

Workaround: In vCenter Server 7.0, you can configure Lockdown Mode and manage Lockdown Mode exception user list by using a security host profile.

When a host profile is applied to a cluster, Enhanced vMotion Compatibility (EVC) settings are missing from the ESXi hosts

Some settings in the VMware config file `/etc/vmware/config` are not managed by Host Profiles and are blocked, when the config file is modified. As a result, when the host profile is applied to a cluster, the EVC settings are lost, which causes loss of EVC functionalities. For example, unmasked CPUs can be exposed to workloads.

Workaround: Reconfigure the relevant EVC baseline on cluster to recover the EVC settings.

Using a host profile that defines a core dump partition in vCenter Server 7.0 results in an error

In vCenter Server 7.0, configuring and managing a core dump partition in a host profile is not available. Attempting to apply a host profile that defines a core dump partition, results in the following error: `No valid coredump partition found.`

Workaround: None. In vCenter Server 7.0., Host Profiles supports only file-based core dumps.

If you run the ESXCLI command to unload the firewall module, the hostd service fails and ESXi hosts lose connectivity

If you automate the firewall configuration in an environment that includes multiple ESXi hosts, and run the ESXCLI command `esxcli network firewall unload` that destroys filters and unloads the firewall module, the hostd service fails and ESXi hosts lose connectivity.

Workaround: Unloading the firewall module is not recommended at any time. If you must unload the firewall module, use the following steps:

1. Stop the hostd service by using the command: `/etc/init.d/hostd stop.`
2. Unload the firewall module by using the command: `esxcli network firewall unload.`
3. Perform the required operations.
4. Load the firewall module by using the command: `esxcli network firewall load.`
5. Start the hostd service by using the command: `/etc/init.d/hostd start.`

vSphere Storage vMotion operations might fail in a vSAN environment due to an unauthenticated session of the Network File Copy (NFC) manager

Migrations to a vSAN datastore by using vSphere Storage vMotion of virtual machines that have at least one snapshot and more than one virtual disk with different storage policy might fail. The issue occurs due to an unauthenticated session of the NFC manager because the Simple Object Access Protocol (SOAP) body exceeds the allowed size.

Workaround: First migrate the VM home namespace and just one of the virtual disks. After the operation completes, perform a disk only migration of the remaining 2 disks.

Changes in the properties and attributes of the devices and storage on an ESXi host might not persist after a reboot

If the device discovery routine during a reboot of an ESXi host times out, the jumpstart plug-in might not receive all configuration changes of the devices and storage from all the registered devices on the host. As a result, the process might restore the properties of some devices or storage to the default values after the reboot.

Workaround: Manually restore the changes in the properties of the affected device or storage.

If you use a beta build of ESXi 7.0, ESXi hosts might fail with a purple diagnostic screen during some lifecycle operations

If you use a beta build of ESXi 7.0, ESXi hosts might fail with a purple diagnostic screen during some lifecycle operations such as unloading a driver or switching between ENS mode and native driver mode. For example, if you try to change the ENS mode, in the backtrace you see an error message similar to: `case ENS::INTERRUPT::NoVM_DeviceStateWithGracefulRemove hit BlueScreen: ASSERT bora/vmkernel/main/dlmalloc.c:2733` This issue is specific for beta builds and does not affect release builds such as ESXi 7.0.

Workaround: Update to ESXi 7.0 GA.

You cannot create snapshots of virtual machines due to an error that a digest operation has failed

A rare race condition when an All-Paths-Down (APD) state occurs during the update of the Content Based Read Cache (CBRC) digest file might cause inconsistencies in the digest file. As a result, you cannot create virtual machine snapshots. You see an error such as `An error occurred while saving the snapshot: A digest operation has failed` in the backtrace.

Workaround: Power cycle the virtual machines to trigger a recompute of the CBRC hashes and clear the inconsistencies in the digest file.

If you upgrade your ESXi hosts to version 7.0 Update 3, but your vCenter Server is of an earlier version, Trusted Platform Module (TPM) attestation of the ESXi hosts fails

If you upgrade your ESXi hosts to version 7.0 Update 3, but your vCenter Server is of an earlier version, and you enable TPM, ESXi hosts fail to pass attestation. In the vSphere Client, you see the warning Host TPM attestation alarm. The Elliptic Curve Digital Signature Algorithm (ECDSA) introduced with ESXi 7.0 Update 3 causes the issue when vCenter Server is not of version 7.0 Update 3.

Workaround: Upgrade your vCenter Server to 7.0 Update 3 or acknowledge the alarm.

You see warnings in the boot loader screen about TPM asset tags

If a TPM-enabled ESXi host has no asset tag set on, you might see idle warning messages in the boot loader screen such as:

```
Failed to determine TPM asset tag size: Buffer too smallFailed to measure asset tag into TPM: Buffer too small
```

Workaround: Ignore the warnings or set an asset tag by using the command `$ esxcli hardware tpm tag set -d`

The sensord daemon fails to report ESXi host hardware status

A logic error in the IPMI SDR validation might cause `sensord` to fail to identify a source for power supply information. As a result, when you run the command `vsish -e get /power/hostStats`, you might not see any output.

Workaround: None

If an ESXi host fails with a purple diagnostic screen, the netdump service might stop working

In rare cases, if an ESXi host fails with a purple diagnostic screen, the netdump service might fail with an error such as `NetDump FAILED: Couldn't attach to dump server at IP x.x.x.x.`

Workaround: Configure the VMkernel core dump to use local storage.

You see frequent VMware Fault Domain Manager (FDM) core dumps on multiple ESXi hosts

In some environments, the number of datastores might exceed the FDM file descriptor limit. As a result, you see frequent core dumps on multiple ESXi hosts indicating FDM failure.

Workaround: Increase the FDM file descriptor limit to 2048. You can use the setting `das.config.fdm.maxFds` from the vSphere HA advanced options in the vSphere Client. For more information, see Set Advanced Options.

Virtual machines on a vSAN cluster with enabled NSX-T and a converged vSphere Distributed Switch (CVDS) in a VLAN transport zone cannot power on after a power off

If a secondary site is 95% disk full and VMs are powered off before simulating a secondary site failure, during recovery some of the virtual machines fail to power on. As a result, virtual machines become unresponsive. The issue occurs regardless if site recovery includes adding disks or ESXi hosts or CPU capacity.

Workaround: Select the virtual machines that do not power on and change the network to VM Network from Edit Settings on the VM context menu.

ESXI hosts might fail with a purple diagnostic screen with an error Assert at bora/modules/vmkernel/vmfs/fs6Journal.c:835

In rare cases, for example when running SESparse tests, the number of locks per transaction in a VMFS datastore might exceed the limit of 50 for the `J6_MAX_TXN_LOCKACTIONS` parameter. As a result, ESXi hosts might fail with a purple diagnostic screen with an error `Assert at bora/modules/vmkernel/vmfs/fs6Journal.c:835`.

Workaround: None

If you modify the netq_rss_ens parameter of the nmlx5_core driver, ESXi hosts might fail with a purple diagnostic screen

If you try to enable the `netq_rss_ens` parameter when you configure an enhanced data path on the `nmlx5_core` driver, ESXi hosts might fail with a purple diagnostic screen. The `netq_rss_ens` parameter, which enables NetQ RSS, is disabled by default with a value of `0`.

Workaround: Keep the default value for the `netq_rss_ens` module parameter in the `nmlx5_core` driver.

ESXi might terminate I/O to NVMeOF devices due to errors on all active paths

Occasionally, all active paths to NVMeOF device register I/O errors due to link issues or controller state. If the status of one of the paths changes to Dead, the High Performance Plug-in (HPP) might not select another path if it shows high volume of errors. As a result, the I/O fails.

Workaround: Disable the configuration option **/Misc/HppManageDegradedPaths** to unblock the I/O.

Upgrade to ESXi 7.0 Update 3 might fail due to changed name of the inbox i40enu network driver

Starting with vSphere 7.0 Update 3, the inbox i40enu network driver for ESXi changes name back to i40en. The i40en driver was renamed to i40enu in vSphere 7.0 Update 2, but the name change impacted some upgrade paths. For example, rollup upgrade of ESXi hosts that you manage with baselines and baseline groups from 7.0 Update 2 or 7.0 Update 2a to 7.0 Update 3 fails. In most cases, the i40enu driver upgrades to ESXi 7.0 Update 3 without any additional steps. However, if the driver upgrade fails, you cannot update ESXi hosts that you manage with baselines and baseline groups. You also cannot use host seeding or a vSphere Lifecycle Manager single image to manage the ESXi hosts. If you have already made changes related to the i40enu driver and devices in your system, before upgrading to ESXi 7.0 Update 3, you must uninstall the i40enu VIB or Component on ESXi, or first upgrade ESXi to ESXi 7.0 Update 2c.

Workaround: For more information, see VMware knowledge base article 85982.

SSH access fails after you upgrade to ESXi 7.0 Update 3d

After you upgrade to ESXi 7.0 Update 3d, SSH access might fail in certain conditions due to an update of OpenSSH to version 8.8.

Workaround: For more information, see VMware knowledge base article 88055.

USB device passthrough from ESXi hosts to virtual machines might fail

A USB modem device might simultaneously claim multiple interfaces by the VMkernel and block the device passthrough to VMs.

Workaround: You must apply the USB.quirks advanced configuration on the ESXi host to ignore the NET interface from VMkernel and allow the USB modem to passthrough to VMs. You can apply the configuration in 3 alternative ways:

1. Access the ESXi shell and run the following command: `esxcli system settings advanced set -o /USB/quirks -s 0xvvvv:0xpppp:0:0xffff:UQ_NET_IGNORE | |- Device Product ID |------- Device Vendor ID`
   For example, for the Gemalto M2M GmbH Zoom 4625 Modem(`vid:pid/1e2d:005b`), you can have the command `esxcli system settings advanced set -o /USB/quirks -s 0x1e2d:0x005b:0:0xffff:UQ_NET_IGNORE`
   Reboot the ESXi host.

2. Set the advanced configuration from the vSphere Client or the vSphere Web Client and reboot the ESXi host.
3. Use a Host Profile to apply the advanced configuration.

For more information on the steps, see VMware knowledge base article 80416.

HTTP requests from certain libraries to vSphere might be rejected

The HTTP reverse proxy in vSphere 7.0 enforces stricter standard compliance than in previous releases. This might expose pre-existing problems in some third-party libraries used by applications for SOAP calls to vSphere.

If you develop vSphere applications that use such libraries or include applications that rely on such libraries in your vSphere stack, you might experience connection issues when these libraries send HTTP requests to VMOMI. For example, HTTP requests issued from vijava libraries can take the following form:

```
POST /sdk HTTP/1.1
SOAPAction
Content-Type: text/xml; charset=utf-8
User-Agent: Java/1.8.0_221
```

The syntax in this example violates an HTTP protocol header field requirement that mandates a colon after SOAPAction. Hence, the request is rejected in flight.

Workaround: Developers leveraging noncompliant libraries in their applications can consider using a library that follows HTTP standards instead. For example, developers who use the vijava library can consider using the latest version of the yavijava library instead.

You might see a dump file when using Broadcom driver lsi_msgpt3, lsi_msgpt35 and lsi_mr3

When using the lsi_msgpt3, lsi_msgpt35 and lsi_mr3 controllers, there is a potential risk to see dump file lsuv2-lsi-drivers-plugin-util-zdump. There is an issue when exiting the storelib used in this plugin utility. There is no impact on ESXi operations, you can ignore the dump file.

Workaround: You can safely ignore this message. You can remove the lsuv2-lsi-drivers-plugin with the following command:

```
esxcli software vib remove -n lsuv2-lsiv2-drivers-plugin
```

You might see reboot is not required after configuring SR-IOV of a PCI device in vCenter, but device configurations made by third party extensions might be lost and require reboot to be re-applied.

In ESXi 7.0, SR-IOV configuration is applied without a reboot and the device driver is reloaded. ESXi hosts might have third party extensions perform device configurations that need to run after the device driver is loaded during boot. A reboot is required for those third party extensions to re-apply the device configuration.

Workaround: You must reboot after configuring SR-IOV to apply third party device configurations.

vSphere Client Issues

BIOS manufacturer displays as "--" in the vSphere Client

In the vSphere Client, when you select an ESXi host and navigate to **Configure** > **Hardware** > **Firmware**, you see `--` instead of the BIOS manufacturer name.

Workaround: For more information, see VMware knowledge base article 88937.

vSAN Issues

PR 2962316: vSAN File Service does not support NFSv4 delegations

vSAN File Service does not support NFSv4 delegations in this release.

Workaround: None

PR 3235496: Applications on a vSAN cluster become intermittently unresponsive

If the advanced option `preferHT` is enabled on an AMD server in a vSAN cluster, the virtual CPUs of a virtual machine run on the same last level cache. When the virtual CPUs are all very busy and an NVMe thread to handle I/Os happens to run also on the same last level cache, the NVMe thread takes very long to complete, because it competes for CPU resources with the busy VMs. As a result, the I/O latency is very high and might lead to intermittent unresponsiveness of storage and applications on the vSAN cluster. In the backlog, you see errors such as `Lost access to volume <uuid> due to connectivity issues. Recovery attempt is in progress and outcome will be reported shortly.`

Workaround: Use the command `esxcli system settings advanced set -o /Misc/vmknvmeCwYield -I 0` to avoid competition between the NVMe completion queue and busy virtual CPUs.

VMware ESXi 7.0 Update 3r Release Notes

This document contains the following sections

- Introduction
- What's New
- Earlier Releases of ESXi 7.0
- Patches Contained in This Release
- Patch Download and Installation
- Resolved Issues
- Known Issues from Previous Releases

Introduction

VMware ESXi 7.0 Update 3r | 12 DEC 2024 | Build 24411414 Check for additions and updates to these release notes.

IMPORTANT: If your source system contains hosts of versions between ESXi 7.0 Update 2 and Update 3c, and Intel drivers, before upgrading to ESXi 7.0 Update 3r, see the What's New section of the VMware vCenter Server 7.0 Update 3c Release Notes, because all content in the section is also applicable for vSphere 7.0 Update 3r. Also, see the related VMware knowledge base articles: 86447, 87258, and 87308.

What's New

This release resolves an issue with vSphere vMotion tasks that fail with an error `NamespaceMgr could not lock the db file.`

Earlier Releases of ESXi 7.0

New features, resolved, and known issues of ESXi are described in the release notes for each release. Release notes for earlier releases of ESXi 7.0 are:

- VMware ESXi 7.0, ESXi 7.0 Update 3q Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3p Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3o Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3n Release Notes

- VMware ESXi 7.0, ESXi 7.0 Update 3m Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3l Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3k Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3j Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3i Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3g Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3f Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2a Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2 Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1b Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1a Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1 Release Notes
- VMware ESXi 7.0, ESXi 7.0b Release Notes

For internationalization, compatibility, and open source components, see the VMware vSphere 7.0 Release Notes.

Patches Contained in This Release

This release of ESXi 7.0 Update 3r delivers the following patches:

Build Details

Download Filename:	VMware-ESXi-7.0U3r-24411414-depot.zip
Build:	24411414
Download Size:	382.0 MB
md5sum:	03433d753ef408ce939dd3a59fd80594
sha256checksum:	82724ee9d297a7cecb0f473c27b44b7401e227db99ea0046e15a2cd7a115ade7
Host Reboot Required:	Yes
Virtual Machine Migration or Shutdown Required:	Yes

Components

Component	Bulletin	Category	Severity
ESXi Component - core ESXi VIBs	ESXi_7.0.3-0.130.24411414	Bugfix	Critical
ESXi Install/Upgrade Component	esx-update_7.0.3-0.130.24411414	Bugfix	Critical

IMPORTANT:

- Starting with vSphere 7.0, VMware uses components for packaging VIBs along with bulletins. The `ESXi` and `esx-update` bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.
- When patching ESXi hosts by using VMware Update Manager from a version prior to ESXi 7.0 Update 2, it is strongly recommended to use the rollup bulletin in the patch baseline. If you cannot use the rollup bulletin, be sure to include *all* of the following packages in the patching baseline. If the following packages are not included in the baseline, the update operation fails:
  - VMware-vmkusb_0.1-1vmw.701.0.0.16850804 or higher
  - VMware-vmkata_0.1-1vmw.701.0.0.16850804 or higher
  - VMware-vmkfcoe_1.0.0.2-1vmw.701.0.0.16850804 or higher
  - VMware-NVMeoF-RDMA_1.0.1.2-1vmw.701.0.0.16850804 or higher

Rollup Bulletin

This rollup bulletin contains the latest VIBs with all the fixes after the initial release of ESXi 7.0.

Bulletin ID	Category	Severity	Details
ESXi70U3r-24411414	Bugfix	Critical	Bugfix only

Image Profiles

VMware patch and update releases contain general and critical image profiles. Application of the general release image profile applies to new bug fixes.

Image Profile Name
ESXi-7.0U3r-24411414-standard
ESXi-7.0U3r-24411414-no-tools

ESXi Image

Name and Version	Release Date	Category	Details
ESXi7.0U3r - 24411414	DEC 12 2024	Bugfix	Bugfix only image

Patch Download and Installation

Log in to the Broadcom Support Portal to download this patch.

For download instructions for earlier releases, see Download Broadcom products and software.

In vSphere 7.x, the Update Manager plug-in, used for administering vSphere Update Manager, is replaced with the Lifecycle Manager plug-in. Administrative operations for vSphere Update Manager are still available under the Lifecycle Manager plug-in, along with new capabilities for vSphere Lifecycle Manager.

The typical way to apply patches to ESXi 7.x hosts is by using the vSphere Lifecycle Manager. For details, see About vSphere Lifecycle Manager and vSphere Lifecycle Manager Baselines and Images.

You can also update ESXi hosts without using the Lifecycle Manager plug-in, and use an image profile instead. To do this, you must manually download the patch offline bundle ZIP file.

For details, see Upgrading Hosts by Using ESXCLI Commands, and the VMware ESXi Upgrade guide.

Resolved Issues

The resolved issues are grouped as follows:

ESXi_7.0.3-0.130.24411414

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs Included	• VMware_bootbank_bmcal_7.0.3-0.130.24411414 • VMware_bootbank_esx-dvfilter-generic-fastpath_7.0.3-0.130.24411414 • VMware_bootbank_vdfs_7.0.3-0.130.24411414 • VMware_bootbank_cpu-microcode_7.0.3-0.130.24411414 • VMware_bootbank_gc_7.0.3-0.130.24411414 • VMware_bootbank_vsanhealth_7.0.3-0.130.24411414 • VMware_bootbank_trx_7.0.3-0.130.24411414 • VMware_bootbank_crx_7.0.3-0.130.24411414 • VMware_bootbank_esx-xserver_7.0.3-0.130.24411414 • VMware_bootbank_vsan_7.0.3-0.130.24411414 • VMware_bootbank_native-misc-drivers_7.0.3-0.130.24411414 • VMware_bootbank_esxio-combiner_7.0.3-0.130.24411414 • VMware_bootbank_esx-base_7.0.3-0.130.24411414
PRs Fixed	3459675
CVE numbers	N/A

The ESXi and esx-update bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.

This patch updates the `esx-base` VIB. Due to their dependency with the `esx-base` VIB, the following VIBs are updated with build number and patch version changes, but deliver no fixes: `bmcal`, `esx-dvfilter-generic-fastpath`, `vdfs`, `cpu-microcode`, `gc`, `vsanhealth`, `trx`, `crx`, `esx-xserver`, `vsan`, `native-misc-drivers`, `esxio-combiner` , and `esx-base` . This patch resolves the following issue:

vSphere vMotion tasks fail with an error NamespaceMgr could not lock the db file

In rare cases, when virtual machines are configured with namespaces, an issue with the namespace database might cause migration of such VMs with vSphere vMotion to fail. In the vSphere Client, you see errors such as:

```
Failed to receive migration. The source detected that the destination failed to resume.
```

```
An error occurred restoring the virtual machine state during migration. NamespaceMgr could not lock the db file.
```

The destination ESXi host `vmware.log` shows the following messages:

```
[YYYY-MM-DDTHH:MM:SS] In(05) vmx - [msg.checkpoint.migration.failedReceive] Failed to receive migration.
```

```
[YYYY-MM-DDTHH:MM:SS] In(05) vmx - [msg.namespaceMgr.noLock] NamespaceMgr could not lock the db file.
```

The issue is more likely to occur on VMs with hardware version earlier than 19, and impacts only VMs provisioned on shared datastores other than NFS, such as VMFS, vSAN, and vSphere Virtual Volumes.

This issue was reported as known in KB 369767 and is resolved in this release.

esx-update_7.0.3-0.130.24411414

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_bootbank_loadesx_7.0.3-0.130.24411414 • VMware_bootbank_esx-update_7.0.3-0.130.24411414
PRs Fixed	N/A
CVE numbers	N/A

Due to their dependency on the `esx-base` VIB, the following VIBs are updated with build number and patch version changes, but deliver no fixes: `loadesx` and `esx-update` .

ESXi-7.0U3r-24411414-standard

Profile Name	ESXi-7.0U3r-24411414-standard
Build	For build information, see Patches Contained in This Release.

Affected VIBs	• VMware_bootbank_bmcal_7.0.3-0.130.24411414 • VMware_bootbank_esx-dvfilter-generic-fastpath_7.0.3-0.130.24411414 • VMware_bootbank_vdfs_7.0.3-0.130.24411414 • VMware_bootbank_cpu-microcode_7.0.3-0.130.24411414 • VMware_bootbank_gc_7.0.3-0.130.24411414 • VMware_bootbank_vsanhealth_7.0.3-0.130.24411414 • VMware_bootbank_trx_7.0.3-0.130.24411414 • VMware_bootbank_crx_7.0.3-0.130.24411414 • VMware_bootbank_esx-xserver_7.0.3-0.130.24411414 • VMware_bootbank_vsan_7.0.3-0.130.24411414 • VMware_bootbank_native-misc-drivers_7.0.3-0.130.24411414 • VMware_bootbank_esxio-combiner_7.0.3-0.130.24411414 • VMware_bootbank_esx-base_7.0.3-0.130.24411414 • VMware_bootbank_loadesx_7.0.3-0.130.24411414 • VMware_bootbank_esx-update_7.0.3-0.130.24411414
PRs Fixed	3459675
Related CVE numbers	N/A

This patch updates the following issue:

vSphere vMotion tasks fail with an error NamespaceMgr could not lock the db file

In rare cases, when virtual machines are configured with namespaces, an issue with the namespace database might cause migration of such VMs with vSphere vMotion to fail. In the vSphere Client, you see errors such as:

```
Failed to receive migration. The source detected that the destination failed to resume.
```

```
An error occurred restoring the virtual machine state during migration. NamespaceMgr could not lock the db file.
```

The destination ESXi host `vmware.log` shows the following messages:

```
[YYYY-MM-DDTHH:MM:SS] In(05) vmx - [msg.checkpoint.migration.failedReceive] Failed to receive migration.
```

```
[YYYY-MM-DDTHH:MM:SS] In(05) vmx - [msg.namespaceMgr.noLock] NamespaceMgr could not lock the db file.
```

The issue is more likely to occur on VMs with hardware version earlier than 19, and impacts only VMs provisioned on shared datastores other than NFS, such as VMFS, vSAN, and vSphere Virtual Volumes.

This issue was reported as known in KB 369767 and is resolved in this release.

ESXi-7.0U3r-24411414-no-tools

[YYYY-MM-DDTHH:MM:SS] In(05) vmx - [msg.namespaceMgr.noLock] NamespaceMgr could not lock the db file.
```

The issue is more likely to occur on VMs with hardware version earlier than 19, and impacts only VMs provisioned on shared datastores other than NFS, such as VMFS, vSAN, and vSphere Virtual Volumes.

This issue was reported as known in KB 369767 and is resolved in this release.

ESXi7.0U3r - 24411414

Name	ESXi
Version	ESXi7.0U3r - 24411414
Release Date	DEC 12, 2024
Category	Bugfix
Affected Components	• ESXi Component - core ESXi • ESXi Install/Upgrade
PRs Fixed	3459675
Related CVE numbers	N/A

This patch resolves the issues listed in ESXi_7.0.3-0.130.24411414.

Known Issues from Previous Releases

vSphere Cluster Services Issues

You see compatibility issues in new vCLS VMs deployed in vSphere 7.0 Update 3 environment

The default name for new vCLS VMs deployed in vSphere 7.0 Update 3 environment uses the pattern vCLS-UUID. vCLS VMs created in earlier vCenter Server versions continue to use the pattern vCLS (n). Since the use of parenthesis () is not supported by many solutions that interoperate with vSphere, you might see compatibility issues.

Workaround: Reconfigure vCLS by using retreat mode after updating to vSphere 7.0 Update 3.

Installation, Upgrade, and Migration Issues

The vCenter Upgrade/Migration pre-checks fail with "Unexpected error 87"

The vCenter Server Upgrade/Migration pre-checks fail when the Security Token Service (STS) certificate does not contain a Subject Alternative Name (SAN) field. This situation occurs when you have replaced the vCenter 5.5 Single Sign-On certificate with a custom certificate that has no SAN field, and you attempt to upgrade to vCenter Server 7.0. The upgrade considers the STS certificate invalid and the pre-checks prevent the upgrade process from continuing.

Workaround: Replace the STS certificate with a valid certificate that contains a SAN field then proceed with the vCenter Server 7.0 Upgrade/Migration.

Corrupted VFAT partitions from a vSphere 6.7 environment might cause upgrades to ESXi 7.x to fail

Due to corrupted VFAT partitions from a vSphere 6.7 environment, repartitioning the boot disks of an ESXi host might fail during an upgrade to ESXi 7.x. As a result, you might see the following errors:

When upgrading to ESXi 7.0 Update 3l, the operation fails with a purple diagnostic screen and/or an error such as:

- `An error occurred while backing up VFAT partition files before re-partitioning: Failed to calculate size for temporary Ramdisk: <error>.`
- `An error occurred while backing up VFAT partition files before re-partitioning: Failed to copy files to Ramdisk: <error>.`
  If you use an ISO installer, you see the errors, but no purple diagnostic screen.

When upgrading to an ESXi 7.x version earlier than 7.0 Update 3l, you might see:

- Logs such as `ramdisk (root) is full` in the `vmkwarning.log` file.
- Unexpected rollback to ESXi 6.5 or 6.7 on reboot.
- The `/bootbank` ,`/altbootbank` , and ESX-OSData partitions are not present.

Workaround: You must first remediate the corrupted partitions before completing the upgrade to ESXi 7.x. For more details, see VMware knowledge base article 91136.

Problems upgrading to vSphere 7.0 with pre-existing CIM providers

After upgrade, previously installed 32-bit CIM providers stop working because ESXi requires 64-bit CIM providers. Customers may lose management API functions related to CIMPDK, NDDK (native DDK), HEXDK, VAIODK (IO filters), and see errors related to **uwglibc** dependency.

The syslog reports module missing, "32 bit shared libraries not loaded."

Workaround: There is no workaround. The fix is to download new 64-bit CIM providers from your vendor.

Installation of 7.0 Update 1 drivers on ESXi 7.0 hosts might fail

You cannot install drivers applicable to ESXi 7.0 Update 1 on hosts that run ESXi 7.0 or 7.0b.

The operation fails with an error, such as:

```
VMW_bootbank_qedrntv_3.40.4.0-12vmw.701.0.0.xxxxxxx requires vmkapi_2_7_0_0, but the requirement cannot be satisfied within the ImageProfile. Please refer to the log file for more details.
```

Workaround: Update the ESXi host to 7.0 Update 1. Retry the driver installation.

UEFI booting of ESXi hosts might stop with an error during an update to ESXi 7.0 Update 2 from an earlier version of ESXi 7.0

If you attempt to update your environment to 7.0 Update 2 from an earlier version of ESXi 7.0by using vSphere Lifecycle Manager patch baselines, UEFI booting of ESXi hosts might stop with an error such as:

```
Loading /boot.cfgFailed to load crypto64.efiFatal error: 15 (Not found)
```

Workaround: For more information, see VMware knowledge base articles 83063 and 83107 .

If legacy VIBs are in use on an ESXi host, vSphere Lifecycle Manager cannot extract a desired software specification to seed to a new cluster

With vCenter Server 7.0 Update 2, you can create a new cluster by importing the desired software specification from a single reference host. However, if legacy VIBs are in use on an ESXi host, vSphere Lifecycle Manager cannot extract in

the vCenter Server instance where you create the cluster a reference software specification from such a host. In the `/var/log/lifecycle.log` , you see messages such as:

```
020-11-11T06:54:03Z lifecycle: 1000082644: HostSeeding:499
ERROR Extract depot failed: Checksum doesn't match. Calculated
5b404e28e83b1387841bb417da93c8c796ef2497c8af0f79583fd54e789d8826, expected:
0947542e30b794c721e21fb595f1851b247711d0619c55489a6a8cae6675e796 2020-11-11T06:54:04Z
lifecycle: 1000082644: imagemanagerctl:366 ERROR Extract depot failed.
2020-11-11T06:54:04Z lifecycle: 1000082644: imagemanagerctl:145 ERROR [VibChecksumError]
```

Workaround: Follow the steps described in VMware knowledge base article 83042.

You see a short burst of log messages in the syslog.log after every ESXi boot

After updating to ESXi 7.0 Update 2, you might see a short burst of log messages after every ESXi boot.

Such logs do not indicate any issue with ESXi and you can ignore these messages. For example:

```
2021-01-19T22:44:22Z watchdog-vaai-nasd: '/usr/lib/vmware/nfs/bin/vaai-nasd -f'
exited after 0 seconds (quick failure 127) 12021-01-19T22:44:22Z watchdog-vaai-
nasd: Executing '/usr/lib/vmware/nfs/bin/vaai-nasd -f'2021-01-19T22:44:22.990Z
aainasd[1000051135]: Log for VAAI-NAS Daemon for NFS version=1.0 build=build-00000

vaainasd[1000051135]: DISKLIB-PLUGIN : Not loading plugin /usr/lib/vmware/nas_plugins/
lib64: Not a shared library.
```

Workaround: None

You see warning messages for missing VIBs in vSphere Quick Boot compatibility check reports

After you upgrade to ESXi 7.0 Update 2, if you check vSphere Quick Boot compatibility of your environment by using the `/usr/lib/vmware/loadesx/bin/loadESXCheckCompat.py` command, you might see some warning messages for missing VIBs in the shell. For example:

```
Cannot find VIB(s) ... in the given VIB collection.Ignoring missing reserved VIB(s) ...,
they are removed from reserved VIB IDs.
```

Such warnings do not indicate a compatibility issue.

Workaround: The missing VIB messages can be safely ignored and do not affect the reporting of vSphere Quick Boot compatibility. The final output line of the `loadESXCheckCompat` command unambiguously indicates if the host is compatible.

Auto bootstrapping a cluster that you manage with a vSphere Lifecycle Manager image fails with an error

If you attempt auto bootstrapping a cluster that you manage with a vSphere Lifecycle Manager image to perform a stateful install and overwrite the VMFS partitions, the operation fails with an error. In the support bundle, you see messages such as:

```
2021-02-11T19:37:43Z Host Profiles[265671 opID=MainThread]: ERROR:
EngineModule::ApplyHostConfig. Exception: [Errno 30] Read-only file system
```

Workaround: Follow vendor guidance to clean the VMFS partition in the target host and retry the operation. Alternatively, use an empty disk. For more information on the disk-partitioning utility on ESXi, see VMware knowledge base article 1036609.

Upgrades to ESXi 7.x from 6.5.x and 6.7.0 by using ESXCLI might fail due to a space limitation

Upgrades to ESXi 7.x from 6.5.x and 6.7.0 by using the `esxcli software profile update` or `esxcli software profile install` ESXCLI commands might fail, because the ESXi bootbank might be less than the size of the image profile. In the ESXi Shell or the PowerCLI shell, you see an error such as:

```
[InstallationError]
 The pending transaction requires 244 MB free space, however the maximum supported size is 239 MB.
 Please refer to the log file for more details.
```

The issue also occurs when you attempt an ESXi host upgrade by using the ESXCLI commands `esxcli software vib update` or `esxcli software vib install`.

Workaround: You can perform the upgrade in two steps, by using the `esxcli software profile update` command to update ESXi hosts to ESXi 6.7 Update 1 or later, and then update to 7.0 Update 1c. Alternatively, you can run an upgrade by using an ISO image and the vSphere Lifecycle Manager.

You cannot migrate linked clones across vCenter Servers

If you migrate a linked clone across vCenter Servers, operations such as power on and delete might fail for the source virtual machine with an `Invalid virtual machine state` error.

Workaround: Keep linked clones on the same vCenter Server as the source VM. Alternatively, promote the linked clone to full clone before migration.

Migration across vCenter Servers of virtual machines with many virtual disks and snapshot levels to a datastore on NVMe over TCP storage might fail

Migration across vCenter Servers of virtual machines with more than 180 virtual disks and 32 snapshot levels to a datastore on NVMe over TCP storage might fail. The ESXi host preemptively fails with an error such as `The migration has exceeded the maximum switchover time of 100 second(s)`.

Workaround: None

A virtual machine with enabled Virtual Performance Monitoring Counters (VPMC) might fail to migrate between ESXi hosts

If you try to migrate a virtual machine with enabled VPMC by using vSphere vMotion, the operation might fail if the target host is using some of the counters to compute memory or performance statistics. The operation fails with an error such as `A performance counter used by the guest is not available on the host CPU`.

Workaround: Power off the virtual machine and use cold migration. For more information, see VMware knowledge base article 81191.

If a live VIB install, upgrade, or remove operation immediately precedes an interactive or scripted upgrade to ESXi 7.0 Update 3 by using the installer ISO, the upgrade fails

When a VIB install, upgrade, or remove operation immediately precedes an interactive or scripted upgrade to ESXi 7.0 Update 3 by using the installer ISO, the ConfigStore might not keep some configurations of the upgrade. As a result, ESXi hosts become inaccessible after the upgrade operation, although the upgrade seems successful. To prevent this issue, the ESXi 7.0 Update 3 installer adds a temporary check to block such scenarios. In the ESXi installer console, you see the following error message: `Live VIB installation, upgrade or removal may cause subsequent ESXi upgrade to fail when using the ISO installer`.

Workaround: Use an alternative upgrade method to avoid the issue, such as using ESXCLI or the vSphere Lifecycle Manager.

Smart Card and RSA SecurID authentication might stop working after upgrading to vCenter Server 7.0

If you have configured vCenter Server for either Smart Card or RSA SecurID authentication, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057 before starting the vSphere 7.0 upgrade process. If you do not perform the workaround as described in the KB, you might see the following error messages and Smart Card or RSA SecurID authentication does not work.

"Smart card authentication may stop working. Smart card settings may not be preserved, and smart card authentication may stop working."

or

"RSA SecurID authentication may stop working. RSA SecurID settings may not be preserved, and RSA SecurID authentication may stop working."

Workaround: Before upgrading to vSphere 7.0, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057.

The vlanid property in custom installation scripts might not work

If you use a custom installation script that sets the `vlanid` property to specify a desired VLAN, the property might not take effect on newly installed ESXi hosts. The issue occurs only when a physical NIC is already connected to DHCP when the installation starts. The `vlanid` property works properly when you use a newly connected NIC.

Workaround: Manually set the VLAN from the Direct Console User Interface after you boot the ESXi host. Alternatively, disable the physical NIC and then boot the host.

HPE servers with Trusted Platform Module (TPM) boot, but remote attestation fails

Some HPE servers do not have enough event log space to properly finish TPM remote attestation. As a result, the VMkernel boots, but remote attestation fails due to the truncated log.

Workaround: None.

Upgrading a vCenter Server with an external Platform Services Controller from 6.7u3 to 7.0 fails with VMAFD error

When you upgrade a vCenter Server deployment using an external Platform Services Controller, you converge the Platform Services Controller into a vCenter Server appliance. If the upgrade fails with the error `install.vmafd.vmdir_vdcpromo_error_21`, the VMAFD firstboot process has failed. The VMAFD firstboot process copies the VMware Directory Service Database (data.mdb) from the source Platform Services Controller and replication partner vCenter Server appliance.

Workaround: Disable TCP Segmentation Offload (TSO) and Generic Segmentation Offload (GSO) on the Ethernet adapter of the source Platform Services Controller or replication partner vCenter Server appliance before upgrading a vCenter Server with an external Platform Services Controller. See Knowledge Base article: https://kb.vmware.com/s/article/74678

Smart card and RSA SecurID settings may not be preserved during vCenter Server upgrade

Authentication using RSA SecurID will not work after upgrading to vCenter Server 7.0. An error message will alert you to this issue when attempting to login using your RSA SecurID login.

Workaround: Reconfigure the smart card or RSA SecureID.

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with network error message

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with the error message `IP already exists in the network.` This prevents the migration process from configuring the network parameters on the new vCenter Server appliance. For more information, examine the log file: `/var/log/vmware/upgrade/UpgradeRunner.log`

Workaround:

1. Verify that all Windows Updates have been completed on the source vCenter Server for Windows instance, or disable automatic Windows Updates until after the migration finishes.
2. Retry the migration of vCenter Server for Windows to vCenter Server appliance 7.0.

When you configure the number of virtual functions for an SR-IOV device by using the max_vfs module parameter, the changes might not take effect

In vSphere 7.0, you can configure the number of virtual functions for an SR-IOV device by using the Virtual Infrastructure Management (VIM) API, for example, through the vSphere Client. The task does not require reboot of the ESXi host. After you use the VIM API configuration, if you try to configure the number of SR-IOV virtual functions by using the `max_vfs` module parameter, the changes might not take effect because they are overridden by the VIM API configuration.

Workaround: None. To configure the number of virtual functions for an SR-IOV device, use the same method every time. Use the VIM API or use the `max_vfs` module parameter and reboot the ESXi host.

Upgraded vCenter Server appliance instance does not retain all the secondary networks (NICs) from the source instance

During a major upgrade, if the source instance of the vCenter Server appliance is configured with multiple secondary networks other than the VCHA NIC, the target vCenter Server instance will not retain secondary networks other than the VCHA NIC. If the source instance is configured with multiple NICs that are part of VDS port groups, the NIC configuration will not be preserved during the upgrade. Configurations for vCenter Server appliance instances that are part of the standard port group will be preserved.

Workaround: None. Manually configure the secondary network in the target vCenter Server appliance instance.

After upgrading or migrating a vCenter Server with an external Platform Services Controller, users authenticating using Active Directory lose access to the newly upgraded vCenter Server instance

After upgrading or migrating a vCenter Server with an external Platform Services Controller, if the newly upgraded vCenter Server is not joined to an Active Directory domain, users authenticating using Active Directory will lose access to the vCenter Server instance.

Workaround: Verify that the new vCenter Server instance has been joined to an Active Directory domain. See Knowledge Base article: https://kb.vmware.com/s/article/2118543

Migrating a vCenter Server for Windows with an external Platform Services Controller using an Oracle database fails

If there are non-ASCII strings in the Oracle events and tasks table the migration can fail when exporting events and tasks data. The following error message is provided: UnicodeDecodeError

Workaround: None.

After an ESXi host upgrade, a Host Profile compliance check shows non-compliant status while host remediation tasks fail

The non-compliant status indicates an inconsistency between the profile and the host.

This inconsistency might occur because ESXi 7.0 does not allow duplicate claim rules, but the profile you use contains duplicate rules. For example, if you attempt to use the Host Profile that you extracted from the host before upgrading ESXi

6.5 or ESXi 6.7 to version 7.0 and the Host Profile contains any duplicate claim rules of system default rules, you might experience the problems.

Workaround:

1. Remove any duplicate claim rules of the system default rules from the Host Profile document.
2. Check the compliance status.
3. Remediate the host.
4. If the previous steps do not help, reboot the host.

Error message displays in the vCenter Server Management Interface

After installing or upgrading to vCenter Server 7.0, when you navigate to the Update panel within the vCenter Server Management Interface, the error message "Check the URL and try again" displays. The error message does not prevent you from using the functions within the Update panel, and you can view, stage, and install any available updates.

Workaround: None.

Security Features Issues

Turn off the Service Location Protocol service in ESXi, slpd, to prevent potential security vulnerabilities

Some services in ESXi that run on top of the host operating system, including slpd, the CIM object broker, sfcbd, and the related openwsmand service, have proven security vulnerabilities. VMware has addressed all known vulnerabilities in VMSA-2019-0022 and VMSA-2020-0023, and the fixes are part of the vSphere 7.0 Update 2 release. While sfcbd and openwsmand are disabled by default in ESXi, slpd is enabled by default and you must turn it off, if not necessary, to prevent exposure to a future vulnerability after an upgrade.

Workaround: To turn off the slpd service, run the following PowerCLI commands:

```
$ Get-VMHost | Get-VmHostService | Where-Object {$_.key -eq "slpd"} | Set-VMHostService -policy "off"$ Get-VMHost | Get-VmHostService | Where-Object {$_.key -eq "slpd"} | Stop-VMHostService -Confirm:$false
```

Alternatively, you can use the command `chkconfig slpd off && /etc/init.d/slpd stop`.

The openwsmand service is not on the ESXi services list and you can check the service state by using the following PowerCLI commands:

```
$esx=(Get-EsxCli -vmhost xx.xx.xx.xx -v2)$esx.system.process.list.invoke() | where CommandLine -like '*openwsman*' | select commandline
```

In the ESXi services list, the sfcbd service appears as sfcbd-watchdog.

For more information, see VMware knowledge base articles 76372 and 1025757.

Encrypted virtual machine fails to power on when HA-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled HA on the Trusted Cluster and one or more hosts in the cluster fails attestation, an encrypted virtual machine cannot power on.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Encrypted virtual machine fails to power on when DRS-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled DRS on the Trusted Cluster and one or more hosts in the cluster fails attestation, DRS might try to power on an encrypted virtual machine on an unattested host in the cluster. This operation puts the virtual machine in a locked state.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Migrating or cloning encrypted virtual machines across vCenter Server instances fails when attempting to do so using the vSphere Client

If you try to migrate or clone an encrypted virtual machine across vCenter Server instances using the vSphere Client, the operation fails with the following error message: "The operation is not allowed in the current state."

Workaround: You must use the vSphere APIs to migrate or clone encrypted virtual machines across vCenter Server instances.

Networking Issues

Reduced throughput in networking performance on Intel 82599/X540/X550 NICs

The new queue-pair feature added to ixgben driver to improve networking performance on Intel 82599EB/X540/X550 series NICs might reduce throughput under some workloads in vSphere 7.0 as compared to vSphere 6.7.

Workaround: To achieve the same networking performance as vSphere 6.7, you can disable the queue-pair with a module parameter. To disable the queue-pair, run the command:

```
# esxcli system module parameters set -p "QPair=0,0,0,0..." -m ixgben
```

After running the command, reboot.

One or more I/O devices do not generate interrupts when the AMD IOMMU is in use

If the I/O devices on your ESXi host provide more than a total of 512 distinct interrupt sources, some sources are erroneously assigned an interrupt-remapping table entry (IRTE) index in the AMD IOMMU that is greater than the maximum value. Interrupts from such a source are lost, so the corresponding I/O device behaves as if interrupts are disabled.

Workaround: Use the ESXCLI command `esxcli system settings kernel set -s iovDisableIR -v true` to disable the AMD IOMMU interrupt remapper. Reboot the ESXi host so that the command takes effect.

When you set auto-negotiation on a network adapter, the device might fail

In some environments, if you set link speed to auto-negotiation for network adapters by using the command `esxcli network nic set -a -n vmmicx` , the devices might fail and reboot does not recover connectivity. The issue is specific to a combination of some Intel X710/X722 network adapters, a SFP+ module and a physical switch, where auto-negotiate speed/duplex scenario is not supported.

Workaround: Make sure you use an Intel-branded SFP+ module. Alternatively, use a Direct Attach Copper (DAC) cable.

Solarflare x2542 and x2541 network adapters configured in 1x100G port mode achieve throughput of up to 70Gbps in a vSphere environment

vSphere 7.0 Update 2 supports Solarflare x2542 and x2541 network adapters configured in 1x100G port mode. However, you might see a hardware limitation in the devices that causes the actual throughput to be up to some 70Gbps in a vSphere environment.

Workaround: None

VLAN traffic might fail after a NIC reset

A NIC with PCI device ID 8086:1537 might stop to send and receive VLAN tagged packets after a reset, for example, with a command `vsish -e set /net/pNics/vmnic0/reset 1` .

Workaround: Avoid resetting the NIC. If you already face the issue, use the following commands to restore the VLAN capability, for example at vmnic0:

```
# esxcli network nic software set --tagging=1 -n vmnic0# esxcli network nic software set
--tagging=0 -n vmnic0
```

Any change in the NetQueue balancer settings causes NetQueue to be disabled after an ESXi host reboot

Any change in the NetQueue balancer settings by using the command `esxcli/localcli network nic queue loadbalancer set -n <nicname> --<lb_setting>` causes NetQueue, which is enabled by default, to be disabled after an ESXi host reboot.

Workaround: After a change in the NetQueue balancer settings and host reboot, use the command `configstorecli config current get -c esx -g network -k nics` to retrieve ConfigStore data to verify whether the `/esx/network/nics/net_queue/load_balancer/enable` is working as expected.

After you run the command, you see output similar to:

```
{"mac": "02:00:0e:6d:14:3e","name": "vmnic1","net_queue": { "load_balancer":
{ "dynamic_pool": true, "enable": true }},"virtual_mac": "00:50:56:5a:21:11"}
```

If the output is not as expected, for example `"load_balancer": "enable": false"` , run the following command:

```
esxcli/localcli network nic queue loadbalancer state set -n <nicname> -e true
```

Paravirtual RDMA (PVRDMA) network adapters do not support NSX networking policies

If you configure an NSX distributed virtual port for use in PVRDMA traffic, the RDMA protocol traffic over the PVRDMA network adapters does not comply with the NSX network policies.

Workaround: Do not configure NSX distributed virtual ports for use in PVRDMA traffic.

Rollback from converged vSphere Distributed Switch (VDS) to NSX-T VDS is not supported in vSphere 7.0 Update 3

Rollback from converged VDS that supports both vSphere 7 traffic and NSX-T 3 traffic on the same VDS to one N-VDS for NSX-T traffic is not supported in vSphere 7.0 Update 3.

Workaround: None

If you do not set the nmlx5 network driver module parameter, network connectivity or ESXi hosts might fail

If you do not set the `supported_num_ports` module parameter for the `nmlx5_core` driver on an ESXi host with multiple network adapters of versions Mellanox ConnectX-4, Mellanox ConnectX-5 and Mellanox ConnectX-6, the driver might not allocate sufficient memory for operating all the NIC ports for the host. As a result, you might experience network loss or ESXi host failure with purple diagnostic screen, or both.

Workaround: Set the `supported_num_ports` module parameter value in the `nmlx5_core` network driver equal to the total number of Mellanox ConnectX-4, Mellanox ConnectX-5 and Mellanox ConnectX-6 network adapter ports on the ESXi host.

High throughput virtual machines may experience degradation in network performance when Network I/O Control (NetIOC) is enabled

Virtual machines requiring high network throughput can experience throughput degradation when upgrading from vSphere 6.7 to vSphere 7.0 with NetIOC enabled.

Workaround: Adjust the `ethernetx.ctxPerDev` setting to enable multiple worlds.

IPv6 traffic fails to pass through VMkernel ports using IPsec

When you migrate VMkernel ports from one port group to another, IPv6 traffic does not pass through VMkernel ports using IPsec.

Workaround: Remove the IPsec security association (SA) from the affected server, and then reapply the SA. To learn how to set and remove an IPsec SA, see the *vSphere Security* documentation.

Higher ESX network performance with a portion of CPU usage increase

ESX network performance may increase with a portion of CPU usage.

Workaround: Remove and add the network interface with only 1 rx dispatch queue. For example:

```
esxcli network ip interface remove --interface-name=vmk1
esxcli network ip interface add --interface-name=vmk1 --num-rxqueue=1
```

VM might lose Ethernet traffic after hot-add, hot-remove or storage vMotion

A VM might stop receiving Ethernet traffic after a hot-add, hot-remove or storage vMotion. This issue affects VMs where the uplink of the VNIC has SR-IOV enabled. PVRDMA virtual NIC exhibits this issue when the uplink of the virtual network is a Mellanox RDMA capable NIC and RDMA namespaces are configured.

Workaround: You can hot-remove and hot-add the affected Ethernet NICs of the VM to restore traffic. On Linux guest operating systems, restarting the network might also resolve the issue. If these workarounds have no effect, you can reboot the VM to restore network connectivity.

Change of IP address for a VCSA deployed with static IP address requires that you create the DNS records in advance

With the introduction of the DDNS, the DNS record update only works for VCSA deployed with DHCP configured networking. While changing the IP address of the vCenter server via VAMI, the following error is displayed:

The specified IP address does not resolve to the specified hostname.

Workaround: There are two possible workarounds.

1. Create an additional DNS entry with the same FQDN and desired IP address. Log in to the VAMI and follow the steps to change the IP address.
2. Log in to the VCSA using ssh. Execute the following script:
   `./opt/vmware/share/vami/vami_config_net`
   Use option 6 to change the IP adddress of eth0. Once changed, execute the following script:
   `./opt/likewise/bin/lw-update-dns`
   Restart all the services on the VCSA to update the IP information on the DNS server.

It may take several seconds for the NSX Distributed Virtual Port Group (NSX DVPG) to be removed after deleting the corresponding logical switch in NSX Manager.

As the number of logical switches increases, it may take more time for the NSX DVPG in vCenter Server to be removed after deleting the corresponding logical switch in NSX Manager. In an environment with 12000 logical switches, it takes approximately 10 seconds for an NSX DVPG to be deleted from vCenter Server.

Workaround: None.

Hostd runs out of memory and fails if a large number of NSX Distributed Virtual port groups are created.

In vSphere 7.0, NSX Distributed Virtual port groups consume significantly larger amounts of memory than opaque networks. For this reason, NSX Distributed Virtual port groups can not support the same scale as an opaque network given the same amount of memory.

Workaround:To support the use of NSX Distributed Virtual port groups, increase the amount of memory in your ESXi hosts. If you verify that your system has adequate memory to support your VMs, you can directly increase the memory of `hostd` using the following command.

```
localcli --plugin-dir /usr/lib/vmware/esxcli/int/ sched group setmemconfig --group-path
host/vim/vmvisor/hostd --units mb --min 2048 --max 2048
```

Note that this will cause `hostd` to use memory normally reserved for your environment's VMs. This may have the affect of reducing the number of VMs your ESXi host can support.

DRS may incorrectly launch vMotion if the network reservation is configured on a VM

If the network reservation is configured on a VM, it is expected that DRS only migrates the VM to a host that meets the specified requirements. In a cluster with NSX transport nodes, if some of the transport nodes join the transport zone by NSX-T Virtual Distributed Switch (N-VDS), and others by vSphere Distributed Switch (VDS) 7.0, DRS may incorrectly launch vMotion. You might encounter this issue when:

- The VM connects to an NSX logical switch configured with a network reservation.
- Some transport nodes join transport zone using N-VDS, and others by VDS 7.0, or, transport nodes join the transport zone through different VDS 7.0 instances.

Workaround: Make all transport nodes join the transport zone by N-VDS or the same VDS 7.0 instance.

When adding a VMkernel NIC (vmknic) to an NSX portgroup, vCenter Server reports the error "Connecting VMKernel adapter to a NSX Portgroup on a Stateless host is not a supported operation. Please use Distributed Port Group instead."

- For stateless ESXi on Distributed Virtual Switch (VDS), the vmknic on a NSX port group is blocked. You must instead use a Distributed Port Group.
- For stateful ESXi on VDS, vmknic on NSX port group is supported, but vSAN may have an issue if it is using vmknic on a NSX port group.

Workaround: Use a Distributed Port Group on the same VDS.

Enabling SRIOV from vCenter for QLogic 4x10GE QL41164HFCU CNA might fail

If you navigate to the **Edit Settings** dialog for physical network adapters and attempt to enable SR-IOV, the operation might fail when using QLogic 4x10GE QL41164HFCU CNA. Attempting to enable SR-IOV might lead to a network outage of the ESXi host.

Workaround: Use the following command on the ESXi host to enable SRIOV:

```
esxcfg-module
```

vCenter Server fails if the hosts in a cluster using Distributed Resource Scheduler (DRS) join NSX-T networking by a different Virtual Distributed Switch (VDS) or combination of NSX-T Virtual Distributed Switch (NVDS) and VDS

In vSphere 7.0, when using NSX-T networking on vSphere VDS with a DRS cluster, if the hosts do not join the NSX transport zone by the same VDS or NVDS, it can cause vCenter Server to fail.

Workaround: Have hosts in a DRS cluster join the NSX transport zone using the same VDS or NVDS.

Storage Issues

VMFS datastores are not mounted automatically after disk hot remove and hot insert on HPE Gen10 servers with SmartPQI controllers

When SATA disks on HPE Gen10 servers with SmartPQI controllers without expanders are hot removed and hot inserted back to a different disk bay of the same machine, or when multiple disks are hot removed and hot inserted back in a different order, sometimes a new local name is assigned to the disk. The VMFS datastore on that disk appears as a snapshot and will not be mounted back automatically because the device name has changed.

Workaround: None. SmartPQI controller does not support unordered hot remove and hot insert operations.

VOMA check on NVMe based VMFS datastores fails with error

VOMA check is not supported for NVMe based VMFS datastores and will fail with the error:

```
ERROR: Failed to reserve device. Function not implemented
```

Example:

```
# voma -m vmfs -f check -d /vmfs/devices/disks/: <partition#>
Running VMFS Checker version 2.1 in check mode
Initializing LVM metadata, Basic Checks will be done

Checking for filesystem activity
Performing filesystem liveness check..|Scanning for VMFS-6 host activity (4096 bytes/HB, 1024 HBs).
ERROR: Failed to reserve device. Function not implemented
Aborting VMFS volume check
VOMA failed to check device : General Error
```

Workaround: None. If you need to analyse VMFS metadata, collect it using the `-l` option, and pass to VMware customer support. The command for collecting the dump is:

```
voma -l -f dump -d /vmfs/devices/disks/:<partition#>
```

Using the VM reconfigure API to attach an encrypted First Class Disk to an encrypted virtual machine might fail with error

If an FCD and a VM are encrypted with different crypto keys, your attempts to attach the encrypted FCD to the encrypted VM using the `VM reconfigure API` might fail with the error message:

```
Cannot decrypt disk because key or password is incorrect.
```

Workaround: Use the `attachDisk API` rather than the `VM reconfigure API` to attach an encrypted FCD to an encrypted VM.

ESXi host might get in non responding state if a non-head extent of its spanned VMFS datastore enters the Permanent Device Loss (PDL) state

This problem does not occur when a non-head extent of the spanned VMFS datastore fails along with the head extent. In this case, the entire datastore becomes inaccessible and no longer allows I/Os.

In contrast, when only a non-head extent fails, but the head extent remains accessible, the datastore heartbeat appears to be normal. And the I/Os between the host and the datastore continue. However, any I/Os that depend on the failed non-head extent start failing as well. Other I/O transactions might accumulate while waiting for the failing I/Os to resolve, and cause the host to enter the non responding state.

Workaround: Fix the PDL condition of the non-head extent to resolve this issue.

Virtual NVMe Controller is the default disk controller for Windows 10 guest operating systems

The Virtual NVMe Controller is the default disk controller for the following guest operating systems when using Hardware Version 15 or later:

Windows 10

Windows Server 2016

Windows Server 2019

Some features might not be available when using a Virtual NVMe Controller. For more information, see https://kb.vmware.com/s/article/2147714

Note: Some clients use the previous default of LSI Logic SAS. This includes ESXi host client and PowerCLI.

Workaround: If you need features not available on Virtual NVMe, switch to VMware Paravirtual SCSI (PVSCSI) or LSI Logic SAS. For information on using VMware Paravirtual SCSI (PVSCSI), see https://kb.vmware.com/s/article/1010398

After an ESXi host upgrade to vSphere 7.0, presence of duplicate core claim rules might cause unexpected behavior

Claim rules determine which multipathing plugin, such as NMP, HPP, and so on, owns paths to a particular storage device. ESXi 7.0 does not support duplicate claim rules. However, the ESXi 7.0 host does not alert you if you add duplicate rules to the existing claim rules inherited through an upgrade from a legacy release. As a result of using duplicate rules, storage devices might be claimed by unintended plugins, which can cause unexpected outcome.

Workaround: Do not use duplicate core claim rules. Before adding a new claim rule, delete any existing matching claim rule.

A CNS query with the compliance status filter set might take unusually long time to complete

The CNS QueryVolume API enables you to obtain information about the CNS volumes, such as volume health and compliance status. When you check the compliance status of individual volumes, the results are obtained quickly. However, when you invoke the CNS QueryVolume API to check the compliance status of multiple volumes, several tens or hundreds, the query might perform slowly.

Workaround: Avoid using bulk queries. When you need to get compliance status, query one volume at a time or limit the number of volumes in the query API to 20 or fewer. While using the query, avoid running other CNS operations to get the best performance.

A VMFS datastore backed by an NVMe over Fabrics namespace or device might become permanently inaccessible after recovering from an APD or PDL failure

If a VMFS datastore on an ESXi host is backed by an NVMe over Fabrics namespace or device, in case of an all paths down (APD) or permanent device loss (PDL) failure, the datastore might be inaccessible even after recovery. You cannot access the datastore from either the ESXi host or the vCenter Server system.

Workaround: To recover from this state, perform a rescan on a host or cluster level. For more information, see Perform Storage Rescan.

Deleted CNS volumes might temporarily appear as existing in the CNS UI

After you delete an FCD disk that backs a CNS volume, the volume might still show up as existing in the CNS UI. However, your attempts to delete the volume fail. You might see an error message similar to the following:

```
The object or item referred to could not be found.
```

Workaround: The next full synchronization will resolve the inconsistency and correctly update the CNS UI.

Attempts to attach multiple CNS volumes to the same pod might occasionally fail with an error

When you attach multiple volumes to the same pod simultaneously, the attach operation might occasionally choose the same controller slot. As a result, only one of the operations succeeds, while other volume mounts fail.

Workaround: After Kubernetes retries the failed operation, the operation succeeds if a controller slot is available on the node VM.

Under certain circumstances, while a CNS operation fails, the task status appears as successful in the vSphere Client

This might occur when, for example, you use an incompliant storage policy to create a CNS volume. The operation fails, while the vSphere Client shows the task status as successful.

Workaround: The successful task status in the vSphere Client does not guarantee that the CNS operation succeeded. To make sure the operation succeeded, verify its results.

Unsuccessful delete operation for a CNS persistent volume might leave the volume undeleted on the vSphere datastore

This issue might occur when the CNS Delete API attempts to delete a persistent volume that is still attached to a pod. For example, when you delete the Kubernetes namespace where the pod runs. As a result, the volume gets cleared from CNS and the CNS query operation does not return the volume. However, the volume continues to reside on the datastore and cannot be deleted through the repeated CNS Delete API operations.

Workaround: None.

vCenter Server and vSphere Client Issues

Vendor providers go offline after a PNID change

When you change the vCenter IP address (PNID change), the registered vendor providers go offline.

Workaround: Re-register the vendor providers.

Cross vCenter migration of a virtual machine fails with an error

When you use cross vCenter vMotion to move a VM's storage and host to a different vCenter server instance, you might receive the error `The operation is not allowed in the current state.`

This error appears in the UI wizard after the Host Selection step and before the Datastore Selection step, in cases where the VM has an assigned storage policy containing host-based rules such as encryption or any other IO filter rule.

Workaround: Assign the VM and its disks to a storage policy without host-based rules. You might need to decrypt the VM if the source VM is encrypted. Then retry the cross vCenter vMotion action.

Storage Sensors information in Hardware Health tab shows incorrect values on vCenter UI, host UI, and MOB

When you navigate to **Host > Monitor > Hardware Health > Storage Sensors** on vCenter UI, the storage information displays either incorrect or unknown values. The same issue is observed on the host UI and the MOB path `“runtime.hardwareStatusInfo.storageStatusInfo”` as well.

Workaround: None.

vSphere UI host advanced settings shows the current product locker location as empty with an empty default

vSphere UI host advanced settings shows the current product locker location as empty with an empty default. This is inconsistent as the actual product location `symlink` is created and valid. This causes confusion to the user. The default cannot be corrected from UI.

Workaround: User can use the esxcli command on the host to correct the current product locker location default as below.

1. Remove the existing Product Locker Location setting with: "`esxcli system settings advanced remove -o ProductLockerLocation`"

2. Re-add the Product Locker Location setting with the appropriate default:

2.a. If the ESXi is a full installation, the default value is "`/locker/packages/vmtoolsRepo`" `export PRODUCT_LOCKER_DEFAULT="/locker/packages/vmtoolsRepo"`

2.b. If the ESXi is a PXEboot configuration such as autodeploy, the default value is: "`/vmtoolsRepo`" `export PRODUCT_LOCKER_DEFAULT="/vmtoolsRepo"`

Run the following command to automatically figure out the location: `export PRODUCT_LOCKER_DEFAULT=`readlink /productLocker``

Add the setting: `esxcli system settings advanced add -d "Path to VMware Tools repository" -o ProductLockerLocation -t string -s $PRODUCT_LOCKER_DEFAULT`

You can combine all the above steps in step 2 by issuing the single command:

```
esxcli system settings advanced add -d "Path to VMware Tools repository" -o ProductLockerLocation -t string -s `readlink /productLocker`
```

Linked Software-Defined Data Center (SDDC) vCenter Server instances appear in the on-premises vSphere Client if a vCenter Cloud Gateway is linked to the SDDC.

When a vCenter Cloud Gateway is deployed in the same environment as an on-premises vCenter Server, and linked to an SDDC, the SDDC vCenter Server will appear in the on-premises vSphere Client. This is unexpected behavior and the linked SDDC vCenter Server should be ignored. All operations involving the linked SDDC vCenter Server should be performed on the vSphere Client running within the vCenter Cloud Gateway.

Workaround: None.

Virtual Machine Management Issues

UEFI HTTP booting of virtual machines on ESXi hosts of version earlier than 7.0 Update 2 fails

UEFI HTTP booting of virtual machines is supported only on hosts of version ESXi 7.0 Update 2 and later and VMs with HW version 19 or later.

Workaround: Use UEFI HTTP booting only in virtual machines with HW version 19 or later. Using HW version 19 ensures the virtual machines are placed only on hosts with ESXi version 7.0 Update 2 or later.

Virtual machine snapshot operations fail in vSphere Virtual Volumes datastores on Purity version 5.3.10

Virtual machine snapshot operations fail in vSphere Virtual Volumes datastores on Purity version 5.3.10 with an error such as `An error occurred while saving the snapshot: The VVol target encountered a vendor specific error`. The issue is specific for Purity version 5.3.10.

Workaround: Upgrade to Purity version 6.1.7 or follow vendor recommendations.

The postcustomization section of the customization script runs before the guest customization

When you run the guest customization script for a Linux guest operating system, the `precustomization` section of the customization script that is defined in the customization specification runs before the guest customization and the `postcustomization` section runs after that. If you enable Cloud-Init in the guest operating system of a virtual machine, the `postcustomization` section runs before the customization due to a known issue in Cloud-Init.

Workaround: Disable Cloud-Init and use the standard guest customization.

Group migration operations in vSphere vMotion, Storage vMotion, and vMotion without shared storage fail with error

When you perform group migration operations on VMs with multiple disks and multi-level snapshots, the operations might fail with the error `com.vmware.vc.GenericVmConfigFault Failed waiting for data. Error 195887167. Connection closed by remote host, possibly due to timeout.`

Workaround: Retry the migration operation on the failed VMs one at a time.

Deploying an OVF or OVA template from a URL fails with a 403 Forbidden error

The URLs that contain an HTTP query parameter are not supported. For example, `http://webaddress.com?file=abc.ovf` or the Amazon pre-signed S3 URLs.

Workaround: Download the files and deploy them from your local file system.

The third level of nested objects in a virtual machine folder is not visible

Perform the following steps:

1. Navigate to a data center and create a virtual machine folder.
2. In the virtual machine folder, create a nested virtual machine folder.
3. In the second folder, create another nested virtual machine, virtual machine folder, vApp, or VM Template.

As a result, from the VMs and Templates inventory tree you cannot see the objects in the third nested folder.

Workaround: To see the objects in the third nested folder, navigate to the second nested folder and select the VMs tab.

vSphere HA and Fault Tolerance Issues

VMs in a cluster might be orphaned after recovering from storage inaccessibility such as a cluster wide APD

Some VMs might be in orphaned state after cluster wide APD recovers, even if HA and VMCP are enabled on the cluster.

This issue might be encountered when the following conditions occur simultaneously:

- All hosts in the cluster experience APD and do not recover until VMCP timeout is reached.
- HA primary initiates failover due to APD on a host.
- Power on API during HA failover fails due to one of the following:
  - APD across the same host
  - Cascading APD across the entire cluster
  - Storage issues
  - Resource unavailability
- FDM unregistration and VCs steal VM logic might initiate during a window where FDM has not unregistered the failed VM and VC's host synchronization responds that multiple hosts are reporting the same VM. Both FDM and VC unregister the different registered copies of the same VM from different hosts, causing the VM to be orphaned.

Workaround: You must unregister and reregister the orphaned VMs manually within the cluster after the APD recovers.

If you do not manually reregister the orphaned VMs, HA attempts failover of the orphaned VMs, but it might take between 5 to 10 hours depending on when APD recovers.

The overall functionality of the cluster is not affected in these cases and HA will continue to protect the VMs. This is an anomaly in what gets displayed on VC for the duration of the problem.

vSphere Lifecycle Manager Issues

vSphere Lifecycle Manager and vSAN File Services cannot be simultaneously enabled on a vSAN cluster in vSphere 7.0 release

If vSphere Lifecycle Manager is enabled on a cluster, vSAN File Services cannot be enabled on the same cluster and vice versa. In order to enable vSphere Lifecycle Manager on a cluster, which has VSAN File Services enabled already, first disable vSAN File Services and retry the operation. Please note that if you transition to a cluster that is managed by a single image, vSphere Lifecycle Manager cannot be disabled on that cluster.

Workaround: None.

When a hardware support manager is unavailable, vSphere High Availability (HA) functionality is impacted

If hardware support manager is unavailable for a cluster that you manage with a single image, where a firmware and drivers addon is selected and vSphere HA is enabled, the vSphere HA functionality is impacted. You may experience the following errors.

- Configuring vSphere HA on a cluster fails.
- Cannot complete the configuration of the vSphere HA agent on a host: `Applying HA VIBs on the cluster encountered a failure.`
- Remediating vSphere HA fails: `A general system error occurred: Failed to get Effective Component map.`
- Disabling vSphere HA fails: Delete Solution task failed. `A general system error occurred: Cannot find hardware support package from depot or hardware support manager.`

Workaround:

- If the hardware support manager is temporarily unavailable, perform the following steps.

1. Reconnect the hardware support manager to vCenter Server.
2. Select a cluster from the Hosts and Cluster menu.
3. Select the Configure tab.
4. Under Services, click vSphere Availability.
5. Re-enable vSphere HA.

- If the hardware support manager is permanently unavailable, perform the following steps.

1. Remove the hardware support manager and the hardware support package from the image specification
2. Re-enable vSphere HA.
3. Select a cluster from the Hosts and Cluster menu.
4. Select the Updates tab.
5. Click Edit .
6. Remove the firmware and drivers addon and click Save.
7. Select the Configure tab.
8. Under Services, click vSphere Availability.
9. Re-enable vSphere HA.

I/OFilter is not removed from a cluster after a remediation process in vSphere Lifecycle Manager

Removing I/OFilter from a cluster by remediating the cluster in vSphere Lifecycle Manager, fails with the following error message: `iofilter XXX already exists` . The iofilter remains listed as installed.

Workaround:

1. Call IOFilter API `UninstallIoFilter_Task` from the vCenter Server managed object (IoFilterManager).
2. Remediate the cluster in vSphere Lifecycle Manager.
3. Call IOFilter API `ResolveInstallationErrorsOnCluster_Task` from the vCenter Server managed object (IoFilterManager) to update the database.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, adding hosts causes a vSphere HA error state

Adding one or multiple ESXi hosts during a remediation process of a vSphere HA enabled cluster, results in the following error message: `Applying HA VIBs on the cluster encountered a failure.`

Workaround: After the cluster remediation operation has finished, perform one of the following tasks.

- Right-click the failed ESXi host and select *Reconfigure for vSphere HA*.

- Disable and re-enable vSphere HA for the cluster.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, disabling and re-enabling vSphere HA causes a vSphere HA error state

Disabling and re-enabling vSphere HA during remediation process of a cluster, may fail the remediation process due to vSphere HA health checks reporting that hosts don't have vSphere HA VIBs installed. You may see the following error message: `Setting desired image spec for cluster failed.`

Workaround: After the cluster remediation operation has finished, disable and re-enable vSphere HA for the cluster.

Checking for recommended images in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the recommendation generation task could take more than an hour to finish or may appear to hang. The completion time for the recommendation task depends on the number of devices configured on each host and the number of image candidates from the depot that vSphere Lifecycle Manager needs to process before obtaining a valid image to recommend.

Workaround: None.

Checking for hardware compatibility in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the validation report generation task could take up to 30 minutes to finish or may appear to hang. The completion time depends on the number of devices configured on each host and the number of hosts configured in the cluster.

Workaround: None

Incomplete error messages in non-English languages are displayed, when remediating a cluster in vSphere Lifecycle Manager

You can encounter incomplete error messages for localized languages in the vCenter Server user interface. The messages are displayed, after a cluster remediation process in vSphere Lifecycle Manager fails. For example, your can observe the following error message.

The error message in English language: `Virtual machine 'VMC on DELL EMC -FileServer' that runs on cluster 'Cluster-1' reported an issue which prevents entering maintenance mode: Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

The error message in French language: `La VM « VMC on DELL EMC -FileServer », située sur le cluster « {Cluster-1} », a signalé un problème empêchant le passage en mode de maintenance : Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

Workaround: None.

Importing an image with no vendor addon, components, or firmware and drivers addon to a cluster which image contains such elements, does not remove the image elements of the existing image

Only the ESXi base image is replaced with the one from the imported image.

Workaround: After the import process finishes, edit the image, and if needed, remove the vendor addon, components, and firmware and drivers addon.

When you convert a cluster that uses baselines to a cluster that uses a single image, a warning is displayed that vSphere HA VIBs will be removed

Converting a vSphere HA enabled cluster that uses baselines to a cluster that uses a single image, may result a warning message displaying that `vmware-fdm` component will be removed.

Workaround: This message can be ignored. The conversion process installs the `vmware-fdm` component.

If vSphere Update Manager is configured to download patch updates from the Internet through a proxy server, after upgrade to vSphere 7.0 that converts Update Manager to vSphere Lifecycle Manager, downloading patches from VMware patch repository might fail

In earlier releases of vCenter Server you could configure independent proxy settings for vCenter Server and vSphere Update Manager. After an upgrade to vSphere 7.0, vSphere Update Manager service becomes part of the vSphere Lifecycle Manager service. For the vSphere Lifecycle Manager service, the proxy settings are configured from the vCenter Server appliance settings. If you had configured Update Manager to download patch updates from the Internet through a proxy server but the vCenter Server appliance had no proxy setting configuration, after a vCenter Server upgrade to version 7.0, the vSphere Lifecycle Manager fails to connect to the VMware depot and is unable to download patches or updates.

Workaround: Log in to the vCenter Server Appliance Management Interface, https://*vcenter-server-appliance-FQDN-or-IP-address*:5480, to configure proxy settings for the vCenter Server appliance and enable vSphere Lifecycle Manager to use proxy.

Miscellaneous Issues

When applying a host profile with version 6.5 to a ESXi host with version 7.0, the compliance check fails

Applying a host profile with version 6.5 to a ESXi host with version 7.0, results in Coredump file profile reported as not compliant with the host.

Workaround: There are two possible workarounds.

1. When you create a host profile with version 6.5, set an advanced configuration option VMkernel.Boot.autoCreateDumpFile to false on the ESXi host.
2. When you apply an existing host profile with version 6.5, add an advanced configuration option VMkernel.Boot.autoCreateDumpFile in the host profile, configure the option to a fixed policy, and set value to false.

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit minor throughput degradation when Dynamic Receive Side Scaling (DYN_RSS) or Generic RSS (GEN_RSS) feature is turned on

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit less than 5 percent throughput degradation when DYN_RSS and GEN_RSS feature is turned on, which is unlikely to impact normal workloads.

Workaround: You can disable DYN_RSS and GEN_RSS feature with the following commands:

```
# esxcli system module parameters set -m nmlx5_core -p "DYN_RSS=0 GEN_RSS=0"
# reboot
```

RDMA traffic between two VMs on the same host might fail in PVRDMA environment

In a vSphere 7.0 implementation of a PVRDMA environment, VMs pass traffic through the HCA for local communication if an HCA is present. However, loopback of RDMA traffic does not work on qedrntv driver. For instance, RDMA Queue Pairs running on VMs that are configured under same uplink port cannot communicate with each other.

In vSphere 6.7 and earlier, HCA was used for local RDMA traffic if SRQ was enabled. vSphere 7.0 uses HCA loopback with VMs using versions of PVRDMA that have SRQ enabled with a minimum of HW v14 using RoCE v2.

The current version of Marvell FastLinQ adapter firmware does not support loopback traffic between QPs of the same PF or port.

Workaround: Required support is being added in the out-of-box driver certified for vSphere 7.0. If you are using the inbox qedrntv driver, you must use a 3-host configuration and migrate VMs to the third host.

Unreliable Datagram traffic QP limitations in qedrntv driver

There are limitations with the Marvell FastLinQ qedrntv RoCE driver and Unreliable Datagram (UD) traffic. UD applications involving bulk traffic might fail with qedrntv driver. Additionally, UD QPs can only work with DMA Memory Regions (MR). Physical MRs or FRMR are not supported. Applications attempting to use physical MR or FRMR along with UD QP fail to pass traffic when used with qedrntv driver. Known examples of such test applications are `ibv_ud_pingpong` and `ib_send_bw`.

Standard RoCE and RoCEv2 use cases in a VMware ESXi environment such as iSER, NVMe-oF (RoCE) and PVRDMA are not impacted by this issue. Use cases for UD traffic are limited and this issue impacts a small set of applications requiring bulk UD traffic.

Marvell FastLinQ hardware does not support RDMA UD traffic offload. In order to meet the VMware PVRDMA requirement to support GSI QP, a restricted software only implementation of UD QP support was added to the qedrntv driver. The goal of the implementation is to provide support for control path GSI communication and is not a complete implementation of UD QP supporting bulk traffic and advanced features.

Since UD support is implemented in software, the implementation might not keep up with heavy traffic and packets might be dropped. This can result in failures with bulk UD traffic.

Workaround: Bulk UD QP traffic is not supported with qedrntv driver and there is no workaround at this time. VMware ESXi RDMA (RoCE) use cases like iSER, NVMe, RDMA and PVRDMA are unaffected by this issue.

Servers equipped with QLogic 578xx NIC might fail when frequently connecting or disconnecting iSCSI LUNs

If you trigger QLogic 578xx NIC iSCSI connection or disconnection frequently in a short time, the server might fail due to an issue with the qfle3 driver. This is caused by a known defect in the device's firmware.

Workaround: None.

ESXi might fail during driver unload or controller disconnect operation in Broadcom NVMe over FC environment

In Broadcom NVMe over FC environment, ESXi might fail during driver unload or controller disconnect operation and display an error message such as: `@BlueScreen: #PF Exception 14 in world 2098707:vmknvmeGener IP 0x4200225021cc addr 0x19`

Workaround: None.

ESXi does not display OEM firmware version number of i350/X550 NICs on some Dell servers

The inbox ixgben driver only recognizes firmware data version or signature for i350/X550 NICs. On some Dell servers the OEM firmware version number is programmed into the OEM package version region, and the inbox ixgben driver does not read this information. Only the 8-digit firmware signature is displayed.

Workaround: To display the OEM firmware version number, install async ixgben driver version 1.7.15 or later.

X710 or XL710 NICs might fail in ESXi

When you initiate certain destructive operations to X710 or XL710 NICs, such as resetting the NIC or manipulating VMKernel's internal device tree, the NIC hardware might read data from non-packet memory.

Workaround: Do not reset the NIC or manipulate vmkernel internal device state.

NVMe-oF does not guarantee persistent VMHBA name after system reboot

NVMe-oF is a new feature in vSphere 7.0. If your server has a USB storage installation that uses vmhba30+ and also has NVMe over RDMA configuration, the VMHBA name might change after a system reboot. This is because the VMHBA name assignment for NVMe over RDMA is different from PCIe devices. ESXi does not guarantee persistence.

Workaround: None.

Backup fails for vCenter database size of 300 GB or greater

If the vCenter database size is 300 GB or greater, the file-based backup will fail with a timeout. The following error message is displayed: `Timeout! Failed to complete in 72000 seconds`

Workaround: None.

A restore of vCenter Server 7.0 which is upgraded from vCenter Server 6.x with External Platform Services Controller to vCenter Server 7.0 might fail

When you restore a vCenter Server 7.0 which is upgraded from 6.x with External Platform Services Controller to vCenter Server 7.0, the restore might fail and display the following error: `Failed to retrieve appliance storage list`

Workaround: During the first stage of the restore process, increase the storage level of the vCenter Server 7.0. For example if the vCenter Server 6.7 External Platform Services Controller setup storage type is small, select storage type large for the restore process.

Enabled SSL protocols configuration parameter is not configured during a host profile remediation process

`Enabled SSL protocols` configuration parameter is not configured during a host profile remediation and only the system default protocol `tlsv1.2` is enabled. This behavior is observed for a host profile with version 7.0 and earlier in a vCenter Server 7.0 environment.

Workaround: To enable TLSV 1.0 or TLSV 1.1 SSL protocols for SFCB, log in to an ESXi host by using SSH, and run the following ESXCLI command: `esxcli system wbem -P <protocol_name>`

Unable to configure Lockdown Mode settings by using Host Profiles

Lockdown Mode cannot be configured by using a security host profile and cannot be applied to multiple ESXi hosts at once. You must manually configure each host.

Workaround: In vCenter Server 7.0, you can configure Lockdown Mode and manage Lockdown Mode exception user list by using a security host profile.

When a host profile is applied to a cluster, Enhanced vMotion Compatibility (EVC) settings are missing from the ESXi hosts

Some settings in the VMware config file `/etc/vmware/config` are not managed by Host Profiles and are blocked, when the config file is modified. As a result, when the host profile is applied to a cluster, the EVC settings are lost, which causes loss of EVC functionalities. For example, unmasked CPUs can be exposed to workloads.

Workaround: Reconfigure the relevant EVC baseline on cluster to recover the EVC settings.

Using a host profile that defines a core dump partition in vCenter Server 7.0 results in an error

In vCenter Server 7.0, configuring and managing a core dump partition in a host profile is not available. Attempting to apply a host profile that defines a core dump partition, results in the following error: `No valid coredump partition found.`

Workaround: None. In vCenter Server 7.0., Host Profiles supports only file-based core dumps.

If you run the ESXCLI command to unload the firewall module, the hostd service fails and ESXi hosts lose connectivity

If you automate the firewall configuration in an environment that includes multiple ESXi hosts, and run the ESXCLI command `esxcli network firewall unload` that destroys filters and unloads the firewall module, the hostd service fails and ESXi hosts lose connectivity.

Workaround: Unloading the firewall module is not recommended at any time. If you must unload the firewall module, use the following steps:

1. Stop the hostd service by using the command:
   `/etc/init.d/hostd stop.`
2. Unload the firewall module by using the command:
   `esxcli network firewall unload.`
3. Perform the required operations.
4. Load the firewall module by using the command:
   `esxcli network firewall load.`
5. Start the hostd service by using the command:
   `/etc/init.d/hostd start.`

vSphere Storage vMotion operations might fail in a vSAN environment due to an unauthenticated session of the Network File Copy (NFC) manager

Migrations to a vSAN datastore by using vSphere Storage vMotion of virtual machines that have at least one snapshot and more than one virtual disk with different storage policy might fail. The issue occurs due to an unauthenticated session of the NFC manager because the Simple Object Access Protocol (SOAP) body exceeds the allowed size.

Workaround: First migrate the VM home namespace and just one of the virtual disks. After the operation completes, perform a disk only migration of the remaining 2 disks.

Changes in the properties and attributes of the devices and storage on an ESXi host might not persist after a reboot

If the device discovery routine during a reboot of an ESXi host times out, the jumpstart plug-in might not receive all configuration changes of the devices and storage from all the registered devices on the host. As a result, the process might restore the properties of some devices or storage to the default values after the reboot.

Workaround: Manually restore the changes in the properties of the affected device or storage.

If you use a beta build of ESXi 7.0, ESXi hosts might fail with a purple diagnostic screen during some lifecycle operations

If you use a beta build of ESXi 7.0, ESXi hosts might fail with a purple diagnostic screen during some lifecycle operations such as unloading a driver or switching between ENS mode and native driver mode. For example, if you try to change the ENS mode, in the backtrace you see an error message similar to: `case ENS::INTERRUPT::NoVM_DeviceStateWithGracefulRemove hit BlueScreen: ASSERT bora/vmkernel/main/dlmalloc.c:2733` This issue is specific for beta builds and does not affect release builds such as ESXi 7.0.

Workaround: Update to ESXi 7.0 GA.

You cannot create snapshots of virtual machines due to an error that a digest operation has failed

A rare race condition when an All-Paths-Down (APD) state occurs during the update of the Content Based Read Cache (CBRC) digest file might cause inconsistencies in the digest file. As a result, you cannot create virtual machine snapshots. You see an error such as `An error occurred while saving the snapshot: A digest operation has failed` in the backtrace.

Workaround: Power cycle the virtual machines to trigger a recompute of the CBRC hashes and clear the inconsistencies in the digest file.

If you upgrade your ESXi hosts to version 7.0 Update 3, but your vCenter Server is of an earlier version, Trusted Platform Module (TPM) attestation of the ESXi hosts fails

If you upgrade your ESXi hosts to version 7.0 Update 3, but your vCenter Server is of an earlier version, and you enable TPM, ESXi hosts fail to pass attestation. In the vSphere Client, you see the warning Host TPM attestation alarm. The Elliptic Curve Digital Signature Algorithm (ECDSA) introduced with ESXi 7.0 Update 3 causes the issue when vCenter Server is not of version 7.0 Update 3.

Workaround: Upgrade your vCenter Server to 7.0 Update 3 or acknowledge the alarm.

You see warnings in the boot loader screen about TPM asset tags

If a TPM-enabled ESXi host has no asset tag set on, you might see idle warning messages in the boot loader screen such as:

```
Failed to determine TPM asset tag size: Buffer too smallFailed to measure asset tag into TPM: Buffer too small
```

Workaround: Ignore the warnings or set an asset tag by using the command `$ esxcli hardware tpm tag set -d`

The sensord daemon fails to report ESXi host hardware status

A logic error in the IPMI SDR validation might cause `sensord` to fail to identify a source for power supply information. As a result, when you run the command `vsish -e get /power/hostStats` , you might not see any output.

Workaround: None

If an ESXi host fails with a purple diagnostic screen, the netdump service might stop working

In rare cases, if an ESXi host fails with a purple diagnostic screen, the netdump service might fail with an error such as `NetDump FAILED: Couldn't attach to dump server at IP x.x.x.x.`

Workaround: Configure the VMkernel core dump to use local storage.

You see frequent VMware Fault Domain Manager (FDM) core dumps on multiple ESXi hosts

In some environments, the number of datastores might exceed the FDM file descriptor limit. As a result, you see frequent core dumps on multiple ESXi hosts indicating FDM failure.

Workaround: Increase the FDM file descriptor limit to 2048. You can use the setting `das.config.fdm.maxFds` from the vSphere HA advanced options in the vSphere Client. For more information, see Set Advanced Options.

Virtual machines on a vSAN cluster with enabled NSX-T and a converged vSphere Distributed Switch (CVDS) in a VLAN transport zone cannot power on after a power off

If a secondary site is 95% disk full and VMs are powered off before simulating a secondary site failure, during recovery some of the virtual machines fail to power on. As a result, virtual machines become unresponsive. The issue occurs regardless if site recovery includes adding disks or ESXi hosts or CPU capacity.

Workaround: Select the virtual machines that do not power on and change the network to VM Network from Edit Settings on the VM context menu.

ESXI hosts might fail with a purple diagnostic screen with an error Assert at bora/modules/vmkernel/vmfs/fs6Journal.c:835

In rare cases, for example when running SESparse tests, the number of locks per transaction in a VMFS datastore might exceed the limit of 50 for the `J6_MAX_TXN_LOCKACTIONS` parameter. As a result, ESXi hosts might fail with a purple diagnostic screen with an error `Assert at bora/modules/vmkernel/vmfs/fs6Journal.c:835` .

Workaround: None

If you modify the netq_rss_ens parameter of the nmlx5_core driver, ESXi hosts might fail with a purple diagnostic screen

If you try to enable the `netq_rss_ens` parameter when you configure an enhanced data path on the `nmlx5_core` driver, ESXi hosts might fail with a purple diagnostic screen. The `netq_rss_ens` parameter, which enables NetQ RSS, is disabled by default with a value of `0` .

Workaround: Keep the default value for the `netq_rss_ens` module parameter in the `nmlx5_core` driver.

ESXi might terminate I/O to NVMeOF devices due to errors on all active paths

Occasionally, all active paths to NVMeOF device register I/O errors due to link issues or controller state. If the status of one of the paths changes to Dead, the High Performance Plug-in (HPP) might not select another path if it shows high volume of errors. As a result, the I/O fails.

Workaround: Disable the configuration option **/Misc/HppManageDegradedPaths** to unblock the I/O.

Upgrade to ESXi 7.0 Update 3 might fail due to changed name of the inbox i40enu network driver

Starting with vSphere 7.0 Update 3, the inbox i40enu network driver for ESXi changes name back to i40en. The i40en driver was renamed to i40enu in vSphere 7.0 Update 2, but the name change impacted some upgrade paths. For example, rollup upgrade of ESXi hosts that you manage with baselines and baseline groups from 7.0 Update 2 or 7.0 Update 2a to 7.0 Update 3 fails. In most cases, the i40enu driver upgrades to ESXi 7.0 Update 3 without any additional steps. However, if the driver upgrade fails, you cannot update ESXi hosts that you manage with baselines and baseline groups. You also cannot use host seeding or a vSphere Lifecycle Manager single image to manage the ESXi hosts. If you have already made changes related to the i40enu driver and devices in your system, before upgrading to ESXi 7.0 Update 3, you must uninstall the i40enu VIB or Component on ESXi, or first upgrade ESXi to ESXi 7.0 Update 2c.

Workaround: For more information, see VMware knowledge base article 85982.

SSH access fails after you upgrade to ESXi 7.0 Update 3d

After you upgrade to ESXi 7.0 Update 3d, SSH access might fail in certain conditions due to an update of OpenSSH to version 8.8.

Workaround: For more information, see VMware knowledge base article 88055.

USB device passthrough from ESXi hosts to virtual machines might fail

A USB modem device might simultaneously claim multiple interfaces by the VMkernel and block the device passthrough to VMs.

Workaround: You must apply the USB.quirks advanced configuration on the ESXi host to ignore the NET interface from VMkernel and allow the USB modem to passthrough to VMs. You can apply the configuration in 3 alternative ways:

1. Access the ESXi shell and run the following command: `esxcli system settings advanced set -o /USB/quirks -s 0xvvvv:0xpppp:0:0xffff:UQ_NET_IGNORE | |- Device Product ID |------- Device Vendor ID`
   For example, for the Gemalto M2M GmbH Zoom 4625 Modem(`vid:pid/1e2d:005b`), you can have the command `esxcli system settings advanced set` **-o** `/USB/quirks -s 0x1e2d:0x005b:0:0xffff:UQ_NET_IGNORE`
   Reboot the ESXi host.
2. Set the advanced configuration from the vSphere Client or the vSphere Web Client and reboot the ESXi host.
3. Use a Host Profile to apply the advanced configuration.

For more information on the steps, see VMware knowledge base article 80416.

HTTP requests from certain libraries to vSphere might be rejected

The HTTP reverse proxy in vSphere 7.0 enforces stricter standard compliance than in previous releases. This might expose pre-existing problems in some third-party libraries used by applications for SOAP calls to vSphere.

If you develop vSphere applications that use such libraries or include applications that rely on such libraries in your vSphere stack, you might experience connection issues when these libraries send HTTP requests to VMOMI. For example, HTTP requests issued from vijava libraries can take the following form:

```
POST /sdk HTTP/1.1
SOAPAction
Content-Type: text/xml; charset=utf-8
User-Agent: Java/1.8.0_221
```

The syntax in this example violates an HTTP protocol header field requirement that mandates a colon after SOAPAction. Hence, the request is rejected in flight.

Workaround: Developers leveraging noncompliant libraries in their applications can consider using a library that follows HTTP standards instead. For example, developers who use the vijava library can consider using the latest version of the yavijava library instead.

You might see a dump file when using Broadcom driver lsi_msgpt3, lsi_msgpt35 and lsi_mr3

When using the lsi_msgpt3, lsi_msgpt35 and lsi_mr3 controllers, there is a potential risk to see dump file lsuv2-lsi-drivers-plugin-util-zdump. There is an issue when exiting the storelib used in this plugin utility. There is no impact on ESXi operations, you can ignore the dump file.

Workaround: You can safely ignore this message. You can remove the lsuv2-lsi-drivers-plugin with the following command:

```
esxcli software vib remove -n lsuv2-lsiv2-drivers-plugin
```

You might see reboot is not required after configuring SR-IOV of a PCI device in vCenter, but device configurations made by third party extensions might be lost and require reboot to be re-applied.

In ESXi 7.0, SR-IOV configuration is applied without a reboot and the device driver is reloaded. ESXi hosts might have third party extensions perform device configurations that need to run after the device driver is loaded during boot. A reboot is required for those third party extensions to re-apply the device configuration.

Workaround: You must reboot after configuring SR-IOV to apply third party device configurations.

vSphere Client Issues

BIOS manufacturer displays as "--" in the vSphere Client

In the vSphere Client, when you select an ESXi host and navigate to **Configure** > **Hardware** > **Firmware**, you see `--` instead of the BIOS manufacturer name.

Workaround: For more information, see VMware knowledge base article 88937.

vSAN Issues

PR 2962316: vSAN File Service does not support NFSv4 delegations

vSAN File Service does not support NFSv4 delegations in this release.

Workaround: None

PR 3235496: Applications on a vSAN cluster become intermittently unresponsive

If the advanced option `preferHT` is enabled on an AMD server in a vSAN cluster, the virtual CPUs of a virtual machine run on the same last level cache. When the virtual CPUs are all very busy and an NVMe thread to handle I/Os happens to run also on the same last level cache, the NVMe thread takes very long to complete, because it competes for CPU resources with the busy VMs. As a result, the I/O latency is very high and might lead to intermittent unresponsiveness of storage and applications on the vSAN cluster. In the backlog, you see errors such as `Lost access to volume <uuid> due to connectivity issues. Recovery attempt is in progress and outcome will be reported shortly.`

Workaround: Use the command `esxcli system settings advanced set -o /Misc/vmknvmeCwYield -I 0` to avoid competition between the NVMe completion queue and busy virtual CPUs.

VMware ESXi 7.0 Update 3q Release Notes

This document contains the following sections

- Introduction
- What's New
- Earlier Releases of ESXi 7.0
- Product Support Notices
- Patches Contained in This Release
- Patch Download and Installation
- Resolved Issues
- Known Issues

Introduction

VMware ESXi 7.0 Update 3q | 21 MAY 2024 |Build 23794027 Check for additions and updates to these release notes.

IMPORTANT: If your source system contains hosts of versions between ESXi 7.0 Update 2 and Update 3c, and Intel drivers, before upgrading to ESXi 7.0 Update 3q, see the What's New section of the VMware vCenter Server 7.0 Update 3c Release Notes, because all content in the section is also applicable for vSphere 7.0 Update 3q. Also, see the related VMware knowledge base articles: 86447, 87258, and 87308.

What's New

- This release resolves CVE-2024-22273. For more information on this vulnerability and its impact on VMware by Broadcom products, see VMSA-2024-0011.

ESXi 7.0 Update 3q adds support to vSphere Quick Boot for multiple servers, including:

- HPE
  - Alletra Storage Server 4110
  - Alletra Storage Server 4140
  - HPE Cray XD670
  - ProLiant DL110 Gen11

- Dell Inc.
  - MX760c vSAN Ready Node
  - PowerEdge C6615
  - PowerEdge HS5610
  - PowerEdge HS5620
  - PowerEdge XR8610t
  - R7625 vSAN Ready Node
  - VxRail VP-760xa
  - VxRail VS-760
- Cisco Systems Inc.
  - UCSC-C220-M7N
  - UCSC-C240-M7SN
  - UCSX-210C-M7
  - UCSX-410C-M7
- Supermicro
  - SYS-221BT-HNC8R

For the full list of supported servers, see the VMware Compatibility Guide.

Earlier Releases of ESXi 7.0

New features, resolved, and known issues of ESXi are described in the release notes for each release. Release notes for earlier releases of ESXi 7.0 are:

- VMware ESXi 7.0, ESXi 7.0 Update 3p Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3o Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3n Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3m Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3l Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3k Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3j Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3i Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3g Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3f Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2a Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2 Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1b Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1a Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1 Release Notes
- VMware ESXi 7.0, ESXi 7.0b Release Notes

For internationalization, compatibility, and open source components, see the VMware vSphere 7.0 Release Notes.

Product Support Notices

Reduction in the memory usage of the ps command:

In ESXi 7.0 Update 3q, an optimization of memory usage for the pscommand reduces memory required to run the command by up to 96%.

Patches Contained in This Release

This release of ESXi 7.0 Update 3q delivers the following patches:

Build Details

Download Filename:	VMware-ESXi-7.0U3q-23794027-depot.zip
Build:	23794027
Download Size:	574.6 MB
md5sum:	a22098da50aa15f007a59e3501da8083
sha256checksum:	2ece2ea2b11c1fe03ca432612c042235e29ef60b634b090e4c055c33c7637c38
Host Reboot Required:	Yes
Virtual Machine Migration or Shutdown Required:	Yes

Components

Component	Bulletin	Category	Severity
ESXi Component - core ESXi VIBs	ESXi_7.0.3-0.125.23794027	Bugfix	Critical
ESXi Install/Upgrade Component	esx-update_7.0.3-0.125.23794027	Bugfix	Critical
VMware Native AHCI Driver	VMware-ahci_2.0.11-3vmw.703.0.125.23794027	Bugfix	Critical
VMware NVMe over TCP Driver	VMware-NVMeoF-TCP_1.0.0.3-1vmw.703.0.125.23794027	Bugfix	Critical
Network driver for Intel(R) X710/XL710/XXV710/X722 Adapters	Intel-i40en_1.11.1.32-1vmw.703.0.125.23794027	Bugfix	Critical
ESXi Component - core ESXi VIBs	ESXi_7.0.3-0.120.23794019	Security	Critical
ESXi Install/Upgrade Component	esx-update_7.0.3-0.120.23794019	Security	Critical
ESXi Tools Component	VMware-VM-Tools_12.3.5.22544099-23794019	Security	Critical

IMPORTANT:

- Starting with vSphere 7.0, VMware uses components for packaging VIBs along with bulletins. The `ESXi` and `esx-update` bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.
- When patching ESXi hosts by using VMware Update Manager from a version prior to ESXi 7.0 Update 2, it is strongly recommended to use the rollup bulletin in the patch baseline. If you cannot use the rollup bulletin, be sure to include

all of the following packages in the patching baseline. If the following packages are not included in the baseline, the update operation fails:

- VMware-vmkusb_0.1-1vmw.701.0.0.16850804 or higher
- VMware-vmkata_0.1-1vmw.701.0.0.16850804 or higher
- VMware-vmkfcoe_1.0.0.2-1vmw.701.0.0.16850804 or higher
- VMware-NVMeoF-RDMA_1.0.1.2-1vmw.701.0.0.16850804 or higher

Rollup Bulletin

This rollup bulletin contains the latest VIBs with all the fixes after the initial release of ESXi 7.0.

Bulletin ID	Category	Severity	Details
ESXi70U3q-23794027	Bugfix	Critical	Security and Bugfix
ESXi70U3sq-23794019	Security	Critical	Security only

Image Profiles

VMware patch and update releases contain general and critical image profiles. Application of the general release image profile applies to new bug fixes.

Image Profile Name
ESXi-7.0U3q-23794027-standard
ESXi-7.0U3q-23794027-no-tools
ESXi-7.0U3sq-23794019-standard
ESXi-7.0U3sq-23794019-no-tools

ESXi Image

Name and Version	Release Date	Category	Details
ESXi7.0U3q - 23794027	MAY 21 2024	Bugfix	Security and Bugfix image
ESXi7.0U3sq - 23794019	MAY 21 2024	Security	Security only image

For information about the individual components and bulletins, see the Resolved Issues section.

Patch Download and Installation

Log in to the Broadcom Support Portal to download this patch.

For download instructions for earlier releases, see Download Broadcom products and software.

In vSphere 7.x, the Update Manager plug-in, used for administering vSphere Update Manager, is replaced with the Lifecycle Manager plug-in. Administrative operations for vSphere Update Manager are still available under the Lifecycle Manager plug-in, along with new capabilities for vSphere Lifecycle Manager.

The typical way to apply patches to ESXi 7.x hosts is by using the vSphere Lifecycle Manager. For details, see About vSphere Lifecycle Manager and vSphere Lifecycle Manager Baselines and Images.

You can also update ESXi hosts without using the Lifecycle Manager plug-in, and use an image profile instead. To do this, you must manually download the patch offline bundle ZIP file.

For details, see Upgrading Hosts by Using ESXCLI Commands, and the VMware ESXi Upgrade guide.

Resolved Issues

The resolved issues are grouped as follows:

ESXi_7.0.3-0.125.23794027

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs Included	• VMware_bootbank_gc_7.0.3-0.125.23794027 • VMware_bootbank_esx-xserver_7.0.3-0.125.23794027 • VMware_bootbank_esx-dvfilter-generic-fastpath_7.0.3-0.125.23794027 • VMware_bootbank_esxio-combiner_7.0.3-0.125.23794027 • VMware_bootbank_vdfs_7.0.3-0.125.23794027 • VMware_bootbank_crx_7.0.3-0.125.23794027 • VMware_bootbank_esx-ui_2.13.2-22721163 • VMware_bootbank_esx-base_7.0.3-0.125.23794027 • VMware_bootbank_trx_7.0.3-0.125.23794027 • VMware_bootbank_vsanhealth_7.0.3-0.125.23794027 • VMware_bootbank_cpu-microcode_7.0.3-0.125.23794027 • VMware_bootbank_native-misc-drivers_7.0.3-0.125.23794027 • VMware_bootbank_vsan_7.0.3-0.125.23794027 • VMware_bootbank_bmcal_7.0.3-0.125.23794027
PRs Fixed	3269229, 3336578, 3332098, 3324772, 3337108, 3319535, 3336916, 3331375, 3326805, 3335978, 3267977, 3323978, 3331256, 3332691, 3313970, 3312843, 3309601, 3317598, 3323119, 3326739, 3317618, 3244429, 3328641, 3328638, 3328337, 3326300, 3329238, 3328301, 3297696, 3296093, 3317448, 3285491, 3276174, 3297629, 3314959, 3309482, 3320147, 3297625, 3297729, 3311303, 3297704, 3309472, 3297749, 3298709, 3320949, 3310432, 3297774, 3302255, 3270210, 3311302, 3257098, 3311831, 3309603, 3317088, 3321157, 2964964, 3305227, 3318350, 3256083, 3269969, 3317445, 3314400, 3267704, 2760003, 3313882, 3243360, 3293469, 3284876, 3265330, 3303842, 3303855, 3293093, 3309148, 3307580, 3301661, 3304469, 3260297, 3260070, 3297409, 3252235, 3287748, 3306033, 3273752, 3288607, 3289238, 3284916, 3303694, 3284133, 3273653, 3298508, 3289605, 3289669, 3291198, 3240347, 3280468, 3285518, 3283501, 3275377, 3267449, 3282267, 3256992, 3251790, 3275137, 3240662, 3259035, 3259205, 3266912, 3282224, 3273653, 3346924, 3346935, 3346816, 3237506, 3331539, 3271089, 3291105, 3346938, 3312150, 3388772
CVE numbers	CVE-2024-22273

The ESXi and esx-update bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.

Updates the gc, esx-xserver, esx-dvfilter-generic-fastpath, esxio-combiner, vdfs, crx, esx-ui, esx-base, trx, vsanhealth, cpu-microcode, native-misc-drivers, vsan , and bmcal VIBs to resolve the following issues:

PR 3318350: The sfcb service might fail and generate multiple dump files

Due to a NULL reference, the sfcbd service might fail. You see multiple dump core files created at /var/core/sfcb-vmware_bas-zdump .

This issue is resolved in this release.

PR 3317598: A disk in a vSAN cluster might fail without an error and cause unresponsiveness or failure of virtual machines in the cluster

In rare cases, if an I/O is stuck due to a hardware of firmware issue on a disk in a vSAN cluster, and a transient error occurs at the same time, a race between the stuck I/O and the transient error handling might cause a deadlock. vSAN does not process any reports on events after the deadlock and you do not receive any notifications. As a result, virtual machines on the cluster of the affected disk become unresponsiveness or fail without logs or warning.

This issue is resolved in this release.

PR 3273653: In vSphere systems using memory cards larger than 64GB, you might see "Unable to allocate SCSI_Command" log messages

If you use physical memory cards larger than 64GB for your vSphere system, whenever the number of VM count increases, you might see errors for the SCSI command slab and heap allocations such as VSCSI: 590: VSCSI_VmkAccumulateSG failed: Out of memory or Unable to allocate SCSI_Command.

This issue is resolved in this release. The fix applies a scale factor based on the size of the physical memory.

PR 3326739: You do not get debugging logs when the vmkdevmgr service fails

In very rare cases, if the vmkdevmgr service fails and core dumps are not enabled, you might not get debugging logs that help you to identify the underlying issue for the failure.

This issue is resolved in this release. The fix adds an automatic check if core dumps for the vmkdevmgr service are enabled.

PR 3309601: The vSphere Virtual Volumes service might fail with a dump while applying a VM Policy to a VM on an ESXi host

In the rare case when an untracked reference to a vendor provider parameter in a vSphere API for Storage Awareness (VASA) session is accessed after deletion, it might cause dump generation. As a result, the vSphere Virtual Volumes service might fail with a dump while applying a VM Policy to a VM on an ESXi host.

This issue is resolved in this release.

PR 3265330: The VMX service might fail during migration of virtual machines with vSphere Virtual Volumes if the volume closure on the source takes long

In some scenarios, such as virtual machines with vSphere Virtual Volumes and Changed Block Tracking (CBT) or Content Based Read Cache (CBRC) enabled, during storage migration, flushing pending I/Os on volume closure at the source might take long, like 10 sec. If clearing the pending I/Os is not complete by the time the VMX service tries to reach the volumes on the destinations host, the service fails.

This issue is resolved in this release. The fix makes sure that all vSphere Virtual Volumes and disks are closed on the source host before the destination host tries to open them.

PR 3331375: Path to SATA drives might move to permanently lost state during a secure wipe operation

During a secure wipe operation, some SATA drives might not provide proper vital product data (VPD) to queries from the host. As a result, the HPP plug-in might incorrectly interpret changes in the physical media and mark a path for the SATA device as permanently lost.

This issue is resolved in this release.

PR 3328638: An ESXi host might fail with a purple diagnostic screen when probe I/Os fail with a retriable error for a long time

In rare scenarios, if for a long period an adapter or device continues to retry an operation that has failed due to a short-lived disruption such as a transient device error or controller reset, a CPU lockup might occur. As a result, an ESXi host might fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3293469: In the vSphere Client, you see a flat line in the read/write IO latency stats for a vSphere Virtual Volumes datastore

In the vSphere Client, when you navigate to **Monitor >Advanced >Datastore** to see the advanced performance metrics of a virtual machine, you might see a flat line in the read/write I/O latency stats for a vSphere Virtual Volumes datastore. The issue occurs due to incorrect calculation of the counters for the read/write I/O latency as a cumulative average.

This issue is resolved in this release.

PR 3303842: WRITE SAME (16) commands with the unmap bit set fail on thick disks

If information from the VPD Page B2 does not prevent the guest OS from activating the unmap bit in a `WRITE SAME (16)` command on thick disks, the command expectedly fails in a vSphere environment. In addition, if the guest OS does not receive a proper error code, it keeps issuing unmap requests by using `WRITE SAME (16)` , also called block zeroing, and this causes I/O errors.

This issue is resolved in this release. With the fix, VPD Page B2 returns proper reports for `WRITE SAME (16)` with unmap support and the guest OS receives a proper error code when unmap is not supported, to prevent unnecessary unmap attempts by the guest.

PR 3314400: An ESXi host fails with a purple diagnostic screen and message @BlueScreen: NMI IPI: Panic requested by another PCPU

In vSphere environments with NSX Data Center, an additional sanity check of the vmxnet3 driver might cause a port or portset lock that might lead to a lock contention. As a result, an ESXi host might fail with a purple diagnostic screen and message `@BlueScreen: NMI IPI: Panic requested by another PCPU.`

This issue is resolved in this release. The fix removes the unnecessary vmxnet3 driver check.

PR 3346924: Upgrade of VMware NSX fails due to a stale DVSPORT_FLAG_RESERVED flag

In very rare cases, a failed vSphere vMotion task might keep a `DVSPORT_FLAG_RESERVED` flag on a port and prevent upgrades of VMware NSX, because the switch on which the port resides cannot be removed. Only a restart of the ESXi host can clean the flag.

This issue is resolved in this release.

PR 3243360: You do not see ESXi host names in the Integrated Dell Remote Access Controller (iDRAC)

When you run the command `localcli hardware ipmi bmc get` in an iDRAC environment, some of the fields for ESXi host names are empty.

This issue is resolved in this release. The fix updates the IPMI BMC hostname during static IP configuration, when the ESXi host is statically configured and rebooted.

PR 3289605: Deactivated transmit queuing option might prevent you from optimizing networking performance

If the `NetSchedHClkVnicMQ` advanced option for transmit queuing is not active, a VNIC with multiple queues might not be able to utilize all queues and prevent significant enhancement of the throughput.

This issue is resolved in this release. The fix makes the `NetSchedHClkVnicMQ` option active by default.

PR 3346935: Migration of virtual machines might fail when vSphere Network I/O Control is active on an ESXi host port to which container ports are mapped to

In rare cases, migrating virtual machines might fail when vSphere Network I/O Control is active on an ESXi host port to which container ports are mapped to, because a dummy port is created at the destination host.

This issue is resolved in this release.

PR 3301661: An I/O filter provider might show offline because of IOFilterVP memory leak

Due to a memory leak in IOFilterVP, an I/O filter provider for an ESXi host might show offline in the vSphere Client under **Configure** > **Storage**. The issue occurs because the SSL cache might consume all heap memory to process VASA API requests.

This issue is resolved in this release. The fix adds a timeout for SSL caching sessions to prevent the memory leak.

PR 3346816: You cannot update the VIB for the NVIDIA GRID vGPU graphics card without rebooting the ESXi host

In case the VIB for the NVIDIA GRID vGPU graphics card is large, lack of sufficient space allocated for the kernel module might prevent automatic update and the operation requires a manual reboot of the ESXi host to complete.

This issue is resolved in this release.

PR 3309482: vSAN host fails with purple diagnostic screen during reboot or mounting a vSAN disk group

A rare issue might cause an incorrect initialization of an internal attribute of a component during recovery of the vSAN logical log, LLOG. As a result, the vSAN host might fail with purple diagnostic screen and in the logs you see an error such as:

```
VMK_ASSERT(cfDisableAssert || LSNEntryLessThan(entry, cfParams->gcpEntry))
```

This issue is resolved in this release.

PR 3306033: You need to manually open the firewall at ports that are different from the default 514 for TCP/UDP and 1514 for SSL protocols

Starting with ESXi 7.0 Update 3q, when you configure syslog remote hosts, or loghosts, with non-standard ports, the vmsyslogd service automatically creates persistent dynamic firewall rules. You no longer need to manually open the firewall at ports that are different from the default 514 for TCP/UDP and 1514 for SSL protocols respectively. When configuring remote hosts with the standard ports, you still need to enable the syslog firewall ruleset.

This issue is resolved in this release. For more information, see Opening the firewall for syslog emission to remote hosts.

PR 3282267: The hostd service might intermittently fail due to an invalid sensor data record

In rare cases, the Baseboard Management Controller (BMC) might provide an invalid sensor data record to the hostd service and cause it to fail. As a result, ESXi hosts become unresponsive or disconnect from vCenter.

This issue is resolved in this release. The fix implements checks to validate the sensor data record before passing it to the hostd service.

PR 3237506: What If analysis on vSAN Capacity screen shows incorrect values when using RAID5 or RAID6 storage policy

In vSAN cluster **Capacity** screen, the What If analysis might show incorrect free space when the cluster is using a RAID5 or RAID6 storage policy.

This issue is resolved in this release.

PR 3276174: vSphere vMotion operations between ESXi 7.x hosts fail with the error "Destination failed to preopen disks"

If on an ESXi 7.x host you use an older Virtual Volumes storage provider, also called a VASA provider, it might not allow binding multiple vSphere Virtual Volumes in batches to optimize the performance of migration and power on. As a result,

in the vSphere Client you might see the error `Destination failed to preopen disks` when running vSphere vMotion operations between 7.x hosts.

This issue is resolved in this release.

PR 3311831: ESXi hosts intermittently fail with a purple diagnostic screen and the error "Spin count exceeded - possible deadlock"

Due to a rare issue with packets that might be out of order in a TCP connection, you might see ESXi hosts intermittently to fail with a purple diagnostic screen and the error `Spin count exceeded - possible deadlock`. In the `vmkernel.log` file, you see a backtrace for errors in the tcpip stack such as:

```
2023-08-28T02:05:27.920Z cpu96:558792334)0x453c10e1bbf0:

This issue is resolved in this release.

PR 3252235: ESXi hosts might fail to boot due to a rare deadlock between open and rename operations on objects with parent-child relationship

A rename operation locks the source and destination directories based on the object pointer address with the assumption that the parent object has the lower address. In rare cases, the assumption might not be correct and the rename lock can happen for the child first and then the parent, while the open operation locks the parent first and then the child. As a result, a deadlock between the open and rename operations occurs and ESXi hosts fail to boot.

This issue is resolved in this release.

PR 3313970: ESXi hosts might fail with a purple diagnostic screen due to a write lock of the uplink watchdog

During a regular sanity check, the uplink watchdog might hold a write lock that prevents reads from other services and might cause the ESXi host might fail with a purple diagnostic screen. In the backtrace, you see errors such as:

```
Panic Message: @BlueScreen: NMI IPI: Panic requested by another PCPU. RIPOFF(base):RBP:CS

[0x14e1e0(0x420033000000):0x430201d03440:0xf48] (Src 0x4, CPU14).
```

This issue is resolved in this release. The fix replaces the write lock with a read lock for regular sanity checks.

PR 3331539: Migration between NSX segments with many container logical ports might cause an ESXi host to fail with a purple diagnostic screen

A rare race condition between vSphere vMotion tasks on NSX Segments with many container logical ports might cause an ESXi host to fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3240662: Host Profile compliance check throws incorrect error message "IPv4 vmknic gateway configuration doesn't match the specification"

In the vSphere Client, you might see the error `IPv4 vmknic gateway configuration doesn't match the specification` when running a compliance check on a Host Profile. The error remains even when you remediate the Host Profile. However, the default gateway settings are defined from the Host Customization workflows and you should not see such an error message during compliance checks. Disregard the message, as it does not affect the host profile functions.

This issue is resolved in this release.

PR 3271089: Virtual machines with a lightweight delta (LWD) snapshot might fail to start after a failure of the vmx service

In rare cases, if the vmx service fails during the creation of a LWD snapshot, some partially initialized LWD snapshot files might remain on the datastore. As a result, virtual machines with such LWD snapshots might fail to start due to validation failures.

This issue is resolved in this release.

PR 3304469: vSphere vMotion operations might fail due to a rare issue with no namespaces present in the namespacemgr.db file

When a virtual machine is configured with namespaces and for some reason the namespaces table in the `namespacemgr.db` file is empty in the ESXi host database, migration of such a VM by using vSphere vMotion might fail. In the `vmware.log` file, you see errors such as:

```
vmx - NamespaceMgrCheckpoint: No valid queue found while restoring the namespace events.
The migrate type is 1.
```

This issue is resolved in this release.

PR 3291105: While detaching an Enhanced Networking Stack (ENS) port from an ESXi host, the host might fail with a purple diagnostic screen

During deactivation of ENS in scenarios such as an upgrade or a VNIC configuration change, while detaching an ENS port from an ESXi host with active ENS, the port might be removed from the port list and not be available for further reference, which might cause an invalid memory access error. As a result, the ESXi host fails with a purple diagnostic screen.

This issue is resolved in this release.

PR 3346938: After a NSX Distributed Security installation, vSphere vMotion might not restore a switch security filter on the destination side

When you opt to install the Security Only option of NSX Distributed Security, vSphere vMotion might not restore a switch security filter on the destination side and the Address Resolution Protocol (ARP) fails.

This issue is resolved in this release.

PR 3312150: Failover of VMs on vSphere Virtual Volume datastores might fail due to wrong order of metadata from vSphere API for Storage Awareness (VASA) provider

Certain VASA providers might return metadata info in a different order than what an ESXi host requests. As a result, when VMs on a vSphere Virtual Volume datastore fail over to a recovery site, the VMs cannot reboot on the target site.

This issue is resolved in this release. With the fix, even if a VASA provider returns metadata info in a different order from the ESXi host request, failover succeeds.

PR 3328641: An ESXi host might fail with a purple diagnostic screen due to a rare issue during a read-modify-write (RMW) operation

On 512e software emulated devices, when I/O requests are not multiple of 4096, ESXi runs RMW operations. In such cases, the final write I/O issue path can access the write command frame after the write is issued to the target. If the target completes the write request before the issue path accesses the write frame, the write frame is freed. As a result, you might see a Use-After-Free scenario that might lead to failure of the ESXi host with a purple diagnostic screen.

This issue is resolved in this release.

PR 3332098: Asynchronous write operations to a SMB file share on the vSAN File Service might cause data transfer issues

In rare cases, a race condition during asynchronous write operations to a SMB file share on the vSAN File Service might cause data transfer issues such as truncation.

This issue is resolved in this release.

PR 3256992: vSphere vMotion tasks fail for VMs on port groups with promiscuous mode enabled

A rare issue with corrupted network packets that becomes evident in secure network protocols, where packet data integrity is checked upon receipt, might lead to connectivity issues on port groups with promiscuous mode enabled. As a result, you might see vSphere vMotion tasks failing for VMs on such port groups. You see data integrity errors such as `Failed to decrypt ciphertext` in the backtrace.

This issue is resolved in this release.

PR 3244429: Exit Code 127 error in the hostd service might cause an ESXi host to disconnect temporarily from vCenter

Due to an issue in the open source glibc components, attempts by hostd to process the list of installed I/O filters on an ESXi host might intermittently cause an Exit Code 127 error. In the `/var/run/log/syslog.log` , you see lines such as:

```
2022-10-13T08:00:20.180Z watchdog-hostd[<PID>]: 'hostd ++min=0,swapscope=system' exited after X seconds 127
```

As a result, the ESXi host temporarily disconnects from vCenter until the hostd watchdog restarts the service and connectivity restores. The issue has been observed while loading the `vmwarelwd` I/O filter.

This issue is resolved in this release. ESXi 7.0 Update 3q adds a hostd configuration option that allows you to deactivate an I/O filter without removing it from the vCenter system and skip reporting such filters in the host configuration overhead. To use the option, log in to SSH and complete the following steps:

1. Set the `plugins/hostsvc/report_disabled_filters_in_host_config` option in the hostd configuration to `False` as described in VMware knowledge base article 82227.
2. Deactivate the `vmwarelwd` filter by running the following python script directly on the host:
   ```
   import vmware.vsi as vsi
   vsi.set('/iofilters/statusDisabledEvent', {'filterName': 'vmwarelwd', 'failureReason' : 'workaround'})
   ```

PR 3332691: vSAN IOPS performance data not available for VM multi-writer virtual disk

The following performance charts for a vSAN VM multi-writer virtual disk, under **Monitor** > **vSAN** > **Performance** > **Virtual Disks**, are not available: IOPS, IOPS limit, and Delayed Normalized IOPS. These charts are available only for disks without active multi-writer mode.

This issue is resolved in this release.

PR 3288607: An ESXi host might fail with a purple diagnostic screen due to a rare storage heap corruption in NVMe devices

In rare cases, an I/O thread from a NVMe device, such as deleting a virtual machine from a datastore using NVMe devices, might complete before the High-Performance Plug-in (HPP) claims the device to complete the thread. As a result, HPP tries to access a non-existing thread which leads to a failure of the ESXi host with a purple diagnostic screen and an error such as `PSOD @BlueScreen: PANIC bora/vmkernel/main/dlmalloc.c:4763`.

This issue is resolved in this release.

PR 3273752: ESXi hosts fail with a purple diagnostic screen and a #PF Exception 14 in world 2097479:HELPER_SCSI_ error

After a change in the namespace list for a controller, for example the PsaNvmeController, the update semaphore works as expected, but the change might not complete because no lock is available. As a result, the ESXi host fails with a purple diagnostic screen and a `#PF Exception 14 in world 2097479:HELPER_SCSI_ error`.

This issue is resolved in this release.

PR 3267977: You might see spikes in the latency performance metrics after creating a virtual machine disk snapshot

After you create a virtual machine disk snapshot, you might see latency spikes in the vSphere performance charts. Such unusual spikes are due to the recreation of some internal system objects and the restart of the latency performance counters in the storage subsystem.

This issue is resolved in this release. The fix prevents false latency alarms after taking virtual machine disk snapshots.

PR 3305227: If you do not increase the TCP/IP heap memory limit before installation of NSX-T Data Center kernel modules, ESXi hosts might crash

When you install NSX-T Data Center kernel modules on ESXi hosts with high loads, the pre-allocated TCP/IP heap during boot required for the operation might not be sufficient and cause the ESXi host to fail with a purple diagnostic screen. The issue occurs when the TCP/IP heap cannot grow quickly enough to provide a continuous allocation of 2 MB of memory in case of memory fragmentation on such ESXi hosts. As a result, ESXi hosts might fail with a purple diagnostic screen and a `vmkernel.log` error such as

```
Heap: 3707: Heap tcpip (44384680/1073746344): Maximum allowed growth (1048576) too small for size (1203496)
```

The purple diagnostic screen failure is less likely to occur if you put the ESXi host in maintenance mode before the NSX-T Data Center kernel modules installation, as MM significantly reduces the memory pressure.

This issue is partially resolved in this release. Starting from ESXi 7.0 Update 3, if you are planning an NSX-T Data Center installation, you can increase the `TcpipHeapSize` limit pre-allocated during boot to 128 MB. For example, if you want to increase the `TcpipHeapSize` allocation to the maximum, you can use the following steps:

1. Increase the heap size to 128 MB by using the command `esxcfg-advcfg -s 128 /Net/TcpipHeapSize`
2. Confirm that the heap size is 128 MB: `esxcfg-advcfg -g /Net/TcpipHeapSize`
3. Reboot the ESXi host.

To avoid this issue, you can reboot the ESXi host and install NSX-T Data Center with no VMs running.

PR 3328301: ESXi hosts might fail with a purple diagnostic screen due to a race condition in the High Performance Plug-in (HPP)

Due to a rare race condition in HPP, when a storage path failover and device deletion occur at the same time, ESXi hosts might fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3257098: A virtual machine fails with McastFilter_Deactivate error

In very rare cases, when a VM is low on memory, a code path might not initialize all its members on restart and cause the VM to fail with a purple diagnostic screen and an error such as `McastFilter_Deactivate`.

This issue is resolved in this release. Avoid low memory state of VMs to prevent similar issues.

PR 3317448: IPv6 routing disappears after you deactivate router advertisement on an ESXi host and the host loses connectivity

Deactivating IPv6 router advertisements (RA) on the physical network or deselecting the option "Obtain IP Address through Router Advertisement" at the VMkernel level might cause the default route for the VMkernel adapter to disappear, even when you have a static IPv6 address on the adapter. The issue occurs only when the IPv6 prefix of both the static IP address and the prefix specified in the RA message are the same. As a result, ESXi incorrectly removes the route entry for that particular subnet, despite that the static IP address is still active for the same prefix, and the ESXi host loses connectivity.

This issue is resolved in this release. Avoid using the same IPv6 prefix for both a static IP address and addresses that are automatically configured in RA messages to prevent the issue.

PR 3312843: ESXi hosts intermittently disconnect from the vCenter system and the hostd service restarts

If an ESXi host uses only one of the multipath plug-ins, either HPP or NMP, when the hostd service collects telemetry data on scheduled intervals, the call might return a null pointer value. Dereferencing the `nullptr` might lead to a hostd failure, but the service automatically restarts. As a result, you see the ESXi host intermittently disconnected from the vCenter system.

This issue is resolved in this release. The fix adds a `nullptr` check.

PR 3328337: The hostd service might become unresponsive after a restart due to a rare issue with Inter Process Communication (IPC)

If an IPC process has incorrect payload in the IPC packet, for example: an incorrect version in the header, a deadlock in the iSCSI daemon might cause the hostd service to become unresponsive after a hostd restart. As a result, you cannot perform any operations on the affected ESXi host and VMs by using the vSphere Client.

This issue is resolved in this release.

PR 3285491: You cannot use host profiles to configure a path selection policy for disks using Raw Device Mapping

In some cases, when you try to change or configure the path selection policy of multiple virtual machines by using a host profile, the operation fails for VMs using Raw Device Mapping.

This issue is resolved in this release.

PR 3296093:ESXi hosts intermittently fail with a purple diagnostic screen and a PF Exception 14 error

While running an ESXi upgrade, a rare race condition in the device registration during disk initialization might lead to an ESXi host failing with a purple diagnostic screen. In the screen, you see an error such as `@BlueScreen: #PF Exception 14 in world XXXXX:HELPER_SCSI_ IP` and in the backtrace, you see `vmk_ScsiGetDeviceState` and `nmp_DeviceUpdatePathStates`.

This issue is resolved in this release.

PR 3321157: You might see network outages in vSphere systems using Intel i40en physical NICs and with Enhanced data path enabled

On Intel i40en NICs, TSO packets that exceed the Maximum Segment Size (MSS) of 8 segments might cause the NIC to become unresponsive. In rare cases, a TSO packet from a VM or from a vmknic might exceed the 8-segement limit and you might see network outages due to blocked pNIC tx traffic. The issue is more likely to occur in vSphere systems using Intel i40en physical NICs and with Enhanced data path enabled.

This issue is resolved in this release.

PR 3307580: Large TCP segmentation offload (TSO) packets might cause network traffic latency and intermittent loss of connectivity for some virtual machines

Environments with the enhanced data path networking stack mode enabled might see network traffic latency and intermittent loss of connectivity for some virtual machines due to an issue with the handling of large TSO packets.

This issue is resolved in this release.

PR 3275137: Rare data corruption issue in vSphere systems that use service insertion might lead to ESXi host failure

In vSphere systems that use service insertion, an error with the check of the available buffer size before pulling data might lead to data corruption that might cause the ESXi host to fail with a purple diagnostic screen.

This issue is resolved in this release. The fix makes sure that data pull during service insertion runs only if a sufficient buffer exists.

PR 3270210: The Busybox shell on an ESXi host might fail after you disable echo mode

If you enter a command after `stty -echo` , which disables the echo mode on a Busybox sh shell on an ESXi host, the shell might fail with a coredump.

This issue is resolved in this release.

PR 3319535: Virtual machines with independent_nonpersistent disks might become inaccessible after a VM reset

During a reset, a virtual machine with independent_nonpersistent disks deletes existing redo log files and creates a new redo log. The vmx process updates the new .redo settings in-memory, not in the .vmx file, and when the hostd service reads the disk properties from the .vmx file during sync up, it might consider the redo logs inconsistent. As a result, hostd marks the VM as invalid and the VM becomes inaccessible.

This issue is resolved in this release.

PR 3317445: Enhanced Network Datapath (EDP) might reserve too much memory on a large vSphere system and cause resource issues

EDP reservation is linear to the total memory by reserving up to 1.6% of the total. For a VM with high memory reservation in a large vSphere system, such a memory buffer might be too big. For example, if the system has a 100TB of memory, the EDP reservation might be 1.6TB. As a result, you might see resource issues such as not being able to hot-add VNICs to VMs with high memory reservation.

This issue is resolved in this release. The fix sets the EDP reservation limit at 1% of the total memory and puts a 5GB cap on a single memory reservation. You can adjust the memory reservation limit by using the VMKernel boot option `ensMbufPoolMaxMinMB` or by using the following command: `esxcli system settings kernel set -s ensMbufPoolMaxMBPerGB -v <value-in-MB>` . In any case, you must reboot the ESXi host to enable the change.

PR 3283501: SFCB start, stop, and reporting operations fail due to a stale lockfile: /var/run/sfcbd-init.lock

In rare cases, the `sfcbd-init` script, which creates a lockfile `/var/run/sfcbd-init.lock` to prevent multiple instances of the script from running at the same time, receives a SIGPIPE signal, which terminates the script and leaves the lockfile unhandled. As a result, any further attempts to run the script fail because they cannot acquire the lock.

This issue is resolved in this release. The fix adds SIGPIPE to the list of signals handled by the trap command in the `sfcbd-init` script. This ensures that the lock file is cleared even when the script receives a SIGPIPE signal.

PR 3285243: If an NFS server sends a file handle with 0 length during a new directory creation, ESXi hosts might fail with a purple diagnostic screen

On volumes mounted by using NFSv4.1, if the NFS server sends a file handle with length of 0 in response to a new directory request, the ESXi host might fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3317088: You see slow response times in vSphere environments with NVMe SSDs

When a NVMe SSD fails, it does not respond to any commands from the NVMe driver, such as closing outstanding I/Os. As a result, many I/O and NVMe driver commands might remain pending and cause slow response times in the vSphere environment or even failure of upper layer applications.

This issue is resolved in this release. With the fix, the NVMe driver initiates controller or queue reset in case driver commands are not effective, to allow closing of outstanding I/Os.

PR 3302202: You might see placeholders listed in the Guest OS version drop-down menu for new ESXi virtual machines

When creating a new virtual machine, in the **Guest OS version** drop-down menu you might see placeholders such as Windows 12 and Windows Server 2025. You cannot use such placeholders to create new virtual machines.

This issue is resolved in this release.

PR 3289669: You cannot power on a virtual machine after a failed or canceled export of an Open Virtual Format (OVF) file

A rare deadlock caused by a failed or canceled export of a VM as an OVF file might prevent subsequent start of that VM. The VM appears in a **VM_STATE_EXPORTING** state.

This issue is resolved in this release. If the export of an OVF file fails due to a network outage, you cannot prevent the issue, but you can avoid it if you do not manually cancel OVF exports. If you already face the issue, restart the hostd service on the affected ESXi host by either using the SSH command `/etc/init.d/hostd restart` or selecting **Restart Management Agents** under **Troubleshooting options** in the Direct Console User Interface. The restart of the host service stops any operations on the ESXi host.

PR 3313882: Virtual machines and data objects might become inaccessible after an ESXi firewall refresh

In some scenarios, a refresh of the ESXi firewall on vSAN clusters might refer to an incomplete object in the ESXi Configuration Store (ConfigStore) and cause the Reliable Datagram Transport (RDT) and Cluster Monitoring, Membership and Directory Service (CMMDS) firewall rules to be disabled. As a result, some clusters might be isolated and virtual machines and data objects might become inaccessible.

This issue is resolved in this release.

PR 3280714: In the web console of Linux virtual machines, the Caps Lock option does not work consistently

When you enable the Caps Lock option in the web console of a Linux virtual machine, the typing output might not consistently be capital letters.

This issue is resolved in this release.

PR 3287440: ESXi hosts stop responding to tasks from the vSphere Client

Due to a rare race condition with accessing vSphere Distributed Switch data from competing services, ESXi hosts might stop responding to tasks from the vSphere Client. For example, in NSX Data Center for vSphere environments, you might see an error such as `TN Profile attachment to the cluster is in progress` that prevents you from running other tasks.

This issue is resolved in this release.

PR 3282224: VXLAN traffic generated from a guest VM to port 4789 fails

ESXi hosts have VXLAN port 8472 enabled by default and not the UDP port 4789, which is the default for NSX 6.2.3 and later. As a result, traffic to VXLAN port 4789 fails.

This issue is resolved in this release. The fix adds port 4789 to the list of VXLAN ports by default.

PR 3260070: ESXi hosts might fail with a purple diagnostic screen due to a NULL pointer reference in a tardisk object

A NULL pointer violation with `VisorFSTarDoIOInt()` in the backtrace might cause ESXi hosts to fail with a purple diagnostic screen. The issue occurs in the following conditions:

1. A vSphere admin manually logs into the host by using SSH
2. Modifies a tardisk file, for example in `/etc` , without re-writing the file completely
3. Performs an upgrade that replaces a VIB containing that specific file
4. The admin or an ESXi service access the modified file

This issue is resolved in this release.

PR 3284133: ESXi hosts in environments with NVMe PCIe devices might temporarily lose connectivity during collection of diagnostic information

When you use the `vm-support` command to collect information about ESXi systems such as network, storage, and vSAN, logs for the telemetry and persistent events of NVMe PCIe controllers are temporally stored in the ramdisk `/tmp` directory. If your system has many NVMe PCIe devices or the log file is large, the ramdisk `/tmp` directory quickly becomes full. As a result, ESXi hosts in environments with NVMe PCIe devices might temporarily lose connectivity until the `vm-support` collection completes.

This issue is resolved in this release. The fix selects the VMFS datastore with the most free space to store `nvme` logs and compresses each log file to save storage space.

PR 3275377: VBS-enabled Windows VMs might intermittently fail with a blue diagnostic screen on ESXi hosts running on AMD processors

Windows virtual machines with virtualization-based security (VBS) enabled might intermittently fail with a blue diagnostic screen on ESXi hosts running on AMD processors. The BSOD has the following signature:

```
SECURE_KERNEL_ERROR (18b)The secure kernel has encountered a fatal error.
Arguments:
Arg1: 000000000000018c
Arg2: 000000000000100b
Arg3: 0000000000000000
Arg4: 000000000000409b
```

This issue is resolved in this release.

PR 3259205: A stateless ESXi host might lose connection to vCenter after a reboot

During the boot of a stateless ESXi host, in very rare situations, the management vmknic might change unexpectedly and change the IP address of the host. As a result, the host disconnects from vCenter. If you apply a host profile, in the vSphere Client you might see an error such as **Host profile apply failed with error: Error: A specified parameter was not correct: SelectVnic.vnic.Specification.NetStackInstanceKey.**

This issue is resolved in this release.

esx-update_7.0.3-0.125.23794027

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_bootbank_esx-update_7.0.3-0.125.23794027 • VMware_bootbank_loadesx_7.0.3-0.125.23794027

PRs Fixed	3317204
CVE numbers	N/A

Updates the `loadesx` and `esx-update` VIBs.

Intel-i40en_1.11.1.32-1vmw.703.0.125.23794027

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMW_bootbank_i40en_1.11.1.32-1vmw.703.0.125.23794027
PRs Fixed	3266231
CVE numbers	N/A

Updates the `i40en` VIB to resolve the following issue:

PR 3266231: If the Maximum Segment Size (MSS) in a TCP packet is less than 64 bytes, Intel X700 series NICs might drop network connection

Intel X700 series NICs regard TCP packets with MSS less than 64 bytes as malicious. As a result, Intel X700 series NICs might not process the Tx path when a VM tries to send such packets, which breaks network connectivity.

This issue is resolved in this release. The fix makes sure that the Intel i40en driver automatically corrects the MSS to a valid size.

VMware-NVMeoF-TCP_1.0.0.3-1vmw.703.0.125.23794027

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	No
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMW_bootbank_nvmetcp_1.0.0.3-1vmw.703.0.125.23794027
PRs Fixed	3297607, 3281791
CVE numbers	N/A

Updates the `nvmetcp` VIB to resolve the following issue:

PR 3297607: An ESXi host might fail with a purple diagnostic screen while connecting to an NVMe over TCP controller

Due to a rare issue in the nvmetcp driver, an ESXi host might fail with a purple diagnostic screen while connecting to an NVMe over TCP controller. In the backtrace, you see a warning such as `WARNING: NVMFDEV:xxxx Failed to connect controller.`

This issue is resolved in this release.

PR 3281791: I/Os might fail on a NVMe over TCP controller with data digest enabled

If the data digest field exceeds a single memory buffer, the nvmetcp driver might not be able to read it. As a result, the driver might drop the NVMe over TCP connection and trigger a queue reset. If this situation repeats, I/O errors start to occur, which might cause issues such as NVMe over TCP storage becoming inaccessible or applications failing, or in the worst case, the ESXi host might fail with a purple diagnostic screen. In the vmkernel logs, you can see an error such as `Failed to receive data digest: Failure.`

This issue is resolved in this release.

VMware-ahci_2.0.11-3vmw.703.0.125.23794027

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMW_bootbank_vmw-ahci_2.0.11-3vmw.703.0.125.23794027
PRs Fixed	3284149
CVE numbers	N/A

Updates the `vmw-ahci` VIB to resolve the following issue:

PR 3284149: Messages from the vmw_ahci driver flood the vmkernel log

On some servers, an Advanced Host Controller Interface (AHCI) controller might report an unexpected interrupt signal, Port Connect Change Status, very frequently even if no device is connected. As a result, the vmw_ahci driver sends the following message in the vmkernel log files about 100 times every second:

```
vmw_ahci[000000170]:<0> CompletionBottomHalf:hotplug port status: 40, IPM(0), SPD(0), DET(1)
vmw_ahci[000000170]:<0> CompletionBottomHalf:Port Status Reporting Port Connect Enable: Clearing PxSER-
R.DIAG.x
vmw_ahci[000000170]:<0> CompletionBottomHalf:hotplug port status: 40, IPM(0), SPD(0), DET(0)
vmw_ahci[000000170]:<0> CompletionBottomHalf:Port Status Reporting Port Connect Enable: Clearing PxSERR.DIAG.x
```

This issue is resolved in this release. With the fix, the AHCI controller no longer generates Port Connect Change Status interrupt signals and the driver no longer prints such messages.

CVE numbers	CVE-2024-22273

The ESXi and esx-update bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.

Updates the `crx, cpu-microcode, gc, esx-xserver, bmcal, vdfs, native-misc-drivers, trx, vsanhealth, esx-base, vsan, esxio-combiner, esx-ui`, and `esx-dvfilter-generic-fastpath` VIBs to resolve the following issues:

ESXi 7.0 Update 3q provides the following security updates:

- The Python library is updated to version 3.8.18.
- The zlib library is updated to version 1.3.
- The cURL library is updated to version 8.4.0.
- The c-ares C library is updated to version 1.19.1.

ESXi 7.0 Update 3q includes the following Intel microcode:

esx-update_7.0.3-0.120.23794019

Patch Category	Security
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_bootbank_loadesx_7.0.3-0.120.23794019 • VMware_bootbank_esx-update_7.0.3-0.120.23794019
PRs Fixed	N/A
CVE numbers	N/A

Updates the `loadesx` and `esx-update` VIBs.

VMware-VM-Tools_12.3.5.22544099-23794019

Patch Category	Security
Patch Severity	Critical
Host Reboot Required	No
Virtual Machine Migration or Shutdown Required	No
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_locker_tools-light_12.3.5.22544099-23794019
PRs Fixed	3304808
CVE numbers	N/A

Updates the `tools-light` VIB.

VMware Tools Bundling Changes in ESXi 7.0 Update 3q

The following VMware Tools ISO images are bundled with ESXi 7.0 Update 3q:

- **windows.iso**: VMware Tools 12.3.5 supports Windows 7 SP1 or Windows Server 2008 R2 SP1 and later.
- **linux.iso**: VMware Tools 10.3.26 ISO image for Linux OS with **glibc** 2.11 or later.

The following VMware Tools ISO images are available for download:

- VMware Tools 11.0.6:
  - **windows.iso**: for Windows Vista (SP2) and Windows Server 2008 Service Pack 2 (SP2).
- VMware Tools 10.0.12:
  - **winPreVista.iso**: for Windows 2000, Windows XP, and Windows 2003.
  - **linuxPreGLibc25.iso**: supports Linux guest operating systems earlier than Red Hat Enterprise Linux (RHEL) 5, SUSE Linux Enterprise Server (SLES) 11, Ubuntu 7.04, and other distributions with **glibc** version earlier than 2.5.
- **solaris.iso**: VMware Tools image 10.3.10 for Solaris.
- **darwin.iso**: Supports Mac OS X versions 10.11 and later.

Follow the procedures listed in the following documents to download VMware Tools for platforms not bundled with ESXi:

- VMware Tools 12.3.5 Release Notes
- Earlier versions of VMware Tools
- What Every vSphere Admin Must Know About VMware Tools
- VMware Tools for hosts provisioned with Auto Deploy
- Updating VMware Tools

Related CVE numbers	CVE-2024-22273

This patch updates the following issues:

PR 3318350: The sfcb service might fail and generate multiple dump files

Due to a NULL reference, the sfcbd service might fail. You see multiple dump core files created at `/var/core/sfcb-vmware_bas-zdump.`.

This issue is resolved in this release.

PR 3284149: Messages from the vmw_ahci driver flood the vmkernel log

On some servers, an Advanced Host Controller Interface (AHCI) controller might report an unexpected interrupt signal, Port Connect Change Status, very frequently even if no device is connected. As a result, the vmw_ahci driver sends the following message in the vmkernel log files about 100 times every second:

```
vmw_ahci[000000170]:<0> CompletionBottomHalf:hotplug port status: 40, IPM(0), SPD(0), DET(1)
vmw_ahci[000000170]:<0> CompletionBottomHalf:Port Status Reporting Port Connect Enable: Clearing PxSER-
R.DIAG.x
vmw_ahci[000000170]:<0> CompletionBottomHalf:hotplug port status: 40, IPM(0), SPD(0), DET(0)
vmw_ahci[000000170]:<0> CompletionBottomHalf:Port Status Reporting Port Connect Enable: Clearing PxSERR.DIAG.x
```

This issue is resolved in this release. With the fix, the AHCI controller no longer generates Port Connect Change Status interrupt signals and the driver no longer prints such messages.

PR 3297607: An ESXi host might fail with a purple diagnostic screen while connecting to an NVMe over TCP controller

Due to a rare issue in the nvmetcp driver, an ESXi host might fail with a purple diagnostic screen while connecting to an NVMe over TCP controller. In the backtrace, you see a warning such as `WARNING: NVMFDEV:xxxx Failed to connect controller.`.

This issue is resolved in this release.

PR 3281791: I/Os might fail on a NVMe over TCP controller with data digest enabled

If the data digest field exceeds a single memory buffer, the nvmetcp driver might not be able to read it. As a result, the driver might drop the NVMe over TCP connection and trigger a queue reset. If this situation repeats, I/O errors start to occur, which might cause issues such as NVMe over TCP storage becoming inaccessible or applications failing, or in the worst case, the ESXi host might fail with a purple diagnostic screen. In the vmkernel logs, you can see an error such as `Failed to receive data digest: Failure.`

This issue is resolved in this release.

PR 3266231: If the Maximum Segment Size (MSS) in a TCP packet is less than 64 bytes, Intel X700 series NICs might drop network connection

Intel X700 series NICs regard TCP packets with MSS less than 64 bytes as malicious. As a result, Intel X700 series NICs might not process the Tx path when a VM tries to send such packets, which breaks network connectivity.

This issue is resolved in this release. The fix makes sure that the Intel i40en driver automatically corrects the MSS to a valid size.

PR 3317598: A disk in a vSAN cluster might fail without an error and cause unresponsiveness or failure of virtual machines in the cluster

In rare cases, if an I/O is stuck due to a hardware of firmware issue on a disk in a vSAN cluster, and a transient error occurs at the same time, a race between the stuck I/O and the transient error handling might cause a deadlock. vSAN does not process any reports on events after the deadlock and you do not receive any notifications. As a result, virtual machines on the cluster of the affected disk become unresponsiveness or fail without logs or warning.

This issue is resolved in this release.

PR 3273653: In vSphere systems using memory cards larger than 64GB, you might see "Unable to allocate SCSI_Command" log messages

If you use physical memory cards larger than 64GB for your vSphere system, whenever the number of VM count increases, you might see errors for the SCSI command slab and heap allocations such as `VSCSI: 590: VSCSI_VmkAccumulateSG failed: Out of memory` or `Unable to allocate SCSI_Command.`

This issue is resolved in this release. The fix applies a scale factor based on the size of the physical memory.

PR 3326739: You do not get debugging logs when the vmkdevmgr service fails

In very rare cases, if the vmkdevmgr service fails and core dumps are not enabled, you might not get debugging logs that help you to identify the underlying issue for the failure.

This issue is resolved in this release. The fix adds an automatic check if core dumps for the vmkdevmgr service are enabled.

PR 3309601: The vSphere Virtual Volumes service might fail with a dump while applying a VM Policy to a VM on an ESXi host

In the rare case when an untracked reference to a vendor provider parameter in a vSphere API for Storage Awareness (VASA) session is accessed after deletion, it might cause dump generation. As a result, the vSphere Virtual Volumes service might fail with a dump while applying a VM Policy to a VM on an ESXi host.

This issue is resolved in this release.

PR 3265330: The VMX service might fail during migration of virtual machines with vSphere Virtual Volumes if the volume closure on the source takes long

In some scenarios, such as virtual machines with vSphere Virtual Volumes and Changed Block Tracking (CBT) or Content Based Read Cache (CBRC) enabled, during storage migration, flushing pending I/Os on volume closure at the source might take long, like 10 sec. If clearing the pending I/Os is not complete by the time the VMX service tries to reach the volumes on the destinations host, the service fails.

This issue is resolved in this release. The fix makes sure that all vSphere Virtual Volumes and disks are closed on the source host before the destination host tries to open them.

PR 3331375: Path to SATA drives might move to permanently lost state during a secure wipe operation

During a secure wipe operation, some SATA drives might not provide proper vital product data (VPD) to queries from the host. As a result, the HPP plug-in might incorrectly interpret changes in the physical media and mark a path for the SATA device as permanently lost.

This issue is resolved in this release.

PR 3328638: An ESXi host might fail with a purple diagnostic screen when probe I/Os fail with a retriable error for a long time

In rare scenarios, if for a long period an adapter or device continues to retry an operation that has failed due to a short-lived disruption such as a transient device error or controller reset, a CPU lockup might occur. As a result, an ESXi host might fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3293469: In the vSphere Client, you see a flat line in the read/write IO latency stats for a vSphere Virtual Volumes datastore

In the vSphere Client, when you navigate to **Monitor >Advanced >Datastore** to see the advanced performance metrics of a virtual machine, you might see a flat line in the read/write I/O latency stats for a vSphere Virtual Volumes datastore. The issue occurs due to incorrect calculation of the counters for the read/write I/O latency as a cumulative average.

This issue is resolved in this release.

PR 3303842: WRITE SAME (16) commands with the unmap bit set fail on thick disks

If information from the VPD Page B2 does not prevent the guest OS from activating the unmap bit in a `WRITE SAME (16)` command on thick disks, the command expectedly fails in a vSphere environment. In addition, if the guest OS does not receive a proper error code, it keeps issuing unmap requests by using `WRITE SAME (16)` , also called block zeroing, and this causes I/O errors.

This issue is resolved in this release. With the fix, VPD Page B2 returns proper reports for `WRITE SAME (16)` with unmap support and the guest OS receives a proper error code when unmap is not supported, to prevent unnecessary unmap attempts by the guest.

PR 3314400: An ESXi host fails with a purple diagnostic screen and message @BlueScreen: NMI IPI: Panic requested by another PCPU

In vSphere environments with NSX Data Center, an additional sanity check of the vmxnet3 driver might cause a port or portset lock that might lead to a lock contention. As a result, an ESXi host might fail with a purple diagnostic screen and message `@BlueScreen: NMI IPI: Panic requested by another PCPU.`

This issue is resolved in this release. The fix removes the unnecessary vmxnet3 driver check.

PR 3346924: Upgrade of VMware NSX fails due to a stale DVSPORT_FLAG_RESERVED flag

In very rare cases, a failed vSphere vMotion task might keep a `DVSPORT_FLAG_RESERVED` flag on a port and prevent upgrades of VMware NSX, because the switch on which the port resides cannot be removed. Only a restart of the ESXi host can clean the flag.

This issue is resolved in this release.

PR 3243360: You do not see ESXi host names in the Integrated Dell Remote Access Controller (iDRAC)

When you run the command `localcli hardware ipmi bmc get` in an iDRAC environment, some of the fields for ESXi host names are empty.

This issue is resolved in this release. The fix updates the IPMI BMC hostname during static IP configuration, when the ESXi host is statically configured and rebooted.

PR 3289605: Deactivated transmit queuing option might prevent you from optimizing networking performance

If the `NetSchedHClkVnicMQ` advanced option for transmit queuing is not active, a VNIC with multiple queues might not be able to utilize all queues and prevent significant enhancement of the throughput.

This issue is resolved in this release. The fix makes the `NetSchedHClkVnicMQ` option active by default.

PR 3346935: Migration of virtual machines might fail when vSphere Network I/O Control is active on an ESXi host port to which container ports are mapped to

In rare cases, migrating virtual machines might fail when vSphere Network I/O Control is active on an ESXi host port to which container ports are mapped to, because a dummy port is created at the destination host.

This issue is resolved in this release.

PR 3301661: An I/O filter provider might show offline because of IOFilterVP memory leak

Due to a memory leak in IOFilterVP, an I/O filter provider for an ESXi host might show offline in the vSphere Client under **Configure** > **Storage**. The issue occurs because the SSL cache might consume all heap memory to process VASA API requests.

This issue is resolved in this release. The fix adds a timeout for SSL caching sessions to prevent the memory leak.

PR 3346816: You cannot update the VIB for the NVIDIA GRID vGPU graphics card without rebooting the ESXi host

In case the VIB for the NVIDIA GRID vGPU graphics card is large, lack of sufficient space allocated for the kernel module might prevent automatic update and the operation requires a manual reboot of the ESXi host to complete.

This issue is resolved in this release.

PR 3309482: vSAN host fails with purple diagnostic screen during reboot or mounting a vSAN disk group

A rare issue might cause an incorrect initialization of an internal attribute of a component during recovery of the vSAN logical log, LLOG. As a result, the vSAN host might fail with purple diagnostic screen and in the logs you see an error such as:

```
VMK_ASSERT(cfDisableAssert || LSNEntryLessThan(entry, cfParams->gcpEntry))
```

This issue is resolved in this release.

PR 3306033: You need to manually open the firewall at ports that are different from the default 514 for TCP/UDP and 1514 for SSL protocols

Starting with ESXi 7.0 Update 3q, when you configure syslog remote hosts, or loghosts, with non-standard ports, the vmsyslogd service automatically creates persistent dynamic firewall rules. You no longer need to manually open the firewall at ports that are different from the default 514 for TCP/UDP and 1514 for SSL protocols respectively. When configuring remote hosts with the standard ports, you still need to enable the syslog firewall ruleset.

This issue is resolved in this release. For more information, see Opening the firewall for syslog emission to remote hosts.

PR 3282267: The hostd service might intermittently fail due to an invalid sensor data record

In rare cases, the Baseboard Management Controller (BMC) might provide an invalid sensor data record to the hostd service and cause it to fail. As a result, ESXi hosts become unresponsive or disconnect from vCenter.

This issue is resolved in this release. The fix implements checks to validate the sensor data record before passing it to the hostd service.

PR 3237506: What If analysis on vSAN Capacity screen shows incorrect values when using RAID5 or RAID6 storage policy

In vSAN cluster **Capacity** screen, the What If analysis might show incorrect free space when the cluster is using a RAID5 or RAID6 storage policy.

This issue is resolved in this release.

PR 3276174: vSphere vMotion operations between ESXi 7.x hosts fail with the error "Destination failed to preopen disks"

If on an ESXi 7.x host you use an older Virtual Volumes storage provider, also called a VASA provider, it might not allow binding multiple vSphere Virtual Volumes in batches to optimize the performance of migration and power on. As a result, in the vSphere Client you might see the error `Destination failed to preopen disks` when running vSphere vMotion operations between 7.x hosts.

This issue is resolved in this release.

PR 3311831: ESXi hosts intermittently fail with a purple diagnostic screen and the error "Spin count exceeded - possible deadlock"

Due to a rare issue with packets that might be out of order in a TCP connection, you might see ESXi hosts intermittently to fail with a purple diagnostic screen and the error `Spin count exceeded - possible deadlock`. In the `vmkernel.log` file, you see a backtrace for errors in the tcpip stack such as:

```
2023-08-28T02:05:27.920Z cpu96:558792334)0x453c10e1bbf0:

```

This issue is resolved in this release.

PR 3252235: ESXi hosts might fail to boot due to a rare deadlock between open and rename operations on objects with parent-child relationship

A rename operation locks the source and destination directories based on the object pointer address with the assumption that the parent object has the lower address. In rare cases, the assumption might not be correct and the rename lock can happen for the child first and then the parent, while the open operation locks the parent first and then the child. As a result, a deadlock between the open and rename operations occurs and ESXi hosts fail to boot.

This issue is resolved in this release.

PR 3313970: ESXi hosts might fail with a purple diagnostic screen due to a write lock of the uplink watchdog

During a regular sanity check, the uplink watchdog might hold a write lock that prevents reads from other services and might cause the ESXi host might fail with a purple diagnostic screen. In the backtrace, you see errors such as:

```
Panic Message: @BlueScreen: NMI IPI: Panic requested by another PCPU. RIPOFF(base):RBP:CS
[0x14e1e0(0x420033000000):0x430201d03440:0xf48] (Src 0x4, CPU14).
```

This issue is resolved in this release. The fix replaces the write lock with a read lock for regular sanity checks.

PR 3331539: Migration between NSX segments with many container logical ports might cause an ESXi host to fail with a purple diagnostic screen

A rare race condition between vSphere vMotion tasks on NSX Segments with many container logical ports might cause an ESXi host to fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3240662: Host Profile compliance check throws incorrect error message "IPv4 vmknic gateway configuration doesn't match the specification"

In the vSphere Client, you might see the error `IPv4 vmknic gateway configuration doesn't match the specification` when running a compliance check on a Host Profile. The error remains even when you remediate the Host Profile. However, the default gateway settings are defined from the Host Customization workflows and you should not see such an error message during compliance checks. Disregard the message, as it does not affect the host profile functions.

This issue is resolved in this release.

PR 3271089: Virtual machines with a lightweight delta (LWD) snapshot might fail to start after a failure of the vmx service

In rare cases, if the vmx service fails during the creation of a LWD snapshot, some partially initialized LWD snapshot files might remain on the datastore. As a result, virtual machines with such LWD snapshots might fail to start due to validation failures.

This issue is resolved in this release.

PR 3304469: vSphere vMotion operations might fail due to a rare issue with no namespaces present in the namespacemgr.db file

When a virtual machine is configured with namespaces and for some reason the namespaces table in the `namespacemgr.db` file is empty in the ESXi host database, migration of such a VM by using vSphere vMotion might fail. In the `vmware.log` file, you see errors such as:

```
vmx - NamespaceMgrCheckpoint: No valid queue found while restoring the namespace events.
The migrate type is 1.
```

This issue is resolved in this release.

PR 3291105: While detaching an Enhanced Networking Stack (ENS) port from an ESXi host, the host might fail with a purple diagnostic screen

During deactivation of ENS in scenarios such as an upgrade or a VNIC configuration change, while detaching an ENS port from an ESXi host with active ENS, the port might be removed from the port list and not be available for further reference, which might cause an invalid memory access error. As a result, the ESXi host fails with a purple diagnostic screen.

This issue is resolved in this release.

PR 3346938: After a NSX Distributed Security installation, vSphere vMotion might not restore a switch security filter on the destination side

When you opt to install the Security Only option of NSX Distributed Security, vSphere vMotion might not restore a switch security filter on the destination side and the Address Resolution Protocol (ARP) fails.

This issue is resolved in this release.

PR 3312150: Failover of VMs on vSphere Virtual Volume datastores might fail due to wrong order of metadata from vSphere API for Storage Awareness (VASA) provider

Certain VASA providers might return metadata info in a different order than what an ESXi host requests. As a result, when VMs on a vSphere Virtual Volume datastore fail over to a recovery site, the VMs cannot reboot on the target site.

This issue is resolved in this release. With the fix, even if a VASA provider returns metadata info in a different order from the ESXi host request, failover succeeds.

PR 3328641: An ESXi host might fail with a purple diagnostic screen due to a rare issue during a read-modify-write (RMW) operation

On 512e software emulated devices, when I/O requests are not multiple of 4096, ESXi runs RMW operations. In such cases, the final write I/O issue path can access the write command frame after the write is issued to the target. If the target completes the write request before the issue path accesses the write frame, the write frame is freed. As a result, you might see a Use-After-Free scenario that might lead to failure of the ESXi host with a purple diagnostic screen.

This issue is resolved in this release.

PR 3332098: Asynchronous write operations to a SMB file share on the vSAN File Service might cause data transfer issues

In rare cases, a race condition during asynchronous write operations to a SMB file share on the vSAN File Service might cause data transfer issues such as truncation.

This issue is resolved in this release.

PR 3256992: vSphere vMotion tasks fail for VMs on port groups with promiscuous mode enabled

A rare issue with corrupted network packets that becomes evident in secure network protocols, where packet data integrity is checked upon receipt, might lead to connectivity issues on port groups with promiscuous mode enabled. As a result, you might see vSphere vMotion tasks failing for VMs on such port groups. You see data integrity errors such as `Failed to decrypt ciphertext` in the backtrace.

This issue is resolved in this release.

PR 3244429: Exit Code 127 error in the hostd service might cause an ESXi host to disconnect temporarily from vCenter

Due to an issue in the open source glibc components, attempts by hostd to process the list of installed I/O filters on an ESXi host might intermittently cause an Exit Code 127 error. In the `/var/run/log/syslog.log` , you see lines such as:

```
2022-10-13T08:00:20.180Z watchdog-hostd[<PID>]: 'hostd ++min=0,swapscope=system' exited after X seconds 127
```

As a result, the ESXi host temporarily disconnects from vCenter until the hostd watchdog restarts the service and connectivity restores. The issue has been observed while loading the `vmwarelwd` I/O filter.

This issue is resolved in this release. ESXi 7.0 Update 3q adds a hostd configuration option that allows you to deactivate an I/O filter without removing it from the vCenter system and skip reporting such filters in the host configuration overhead. To use the option, log in to SSH and complete the following steps:

1. Set the `plugins/hostsvc/report_disabled_filters_in_host_config` option in the hostd configuration to `False` as described in VMware knowledge base article 82227.

2. Deactivate the `vmwarelwd` filter by running the following python script directly on the host:

```
import vmware.vsi as vsi
vsi.set('/iofilters/statusDisabledEvent', {'filterName': 'vmwarelwd', 'failureReason' :
'workaround'})
```

PR 3332691: vSAN IOPS performance data not available for VM multi-writer virtual disk

The following performance charts for a vSAN VM multi-writer virtual disk, under **Monitor** > **vSAN** > **Performance** > **Virtual Disks**, are not available: IOPS, IOPS limit, and Delayed Normalized IOPS. These charts are available only for disks without active multi-writer mode.

This issue is resolved in this release.

PR 3288607: An ESXi host might fail with a purple diagnostic screen due to a rare storage heap corruption in NVMe devices

In rare cases, an I/O thread from a NVMe device, such as deleting a virtual machine from a datastore using NVMe devices, might complete before the High-Performance Plug-in (HPP) claims the device to complete the thread. As a result, HPP tries to access a non-existing thread which leads to a failure of the ESXi host with a purple diagnostic screen and an error such as `PSOD @BlueScreen: PANIC bora/vmkernel/main/dlmalloc.c:4763`.

This issue is resolved in this release.

PR 3273752: ESXi hosts fail with a purple diagnostic screen and a #PF Exception 14 in world 2097479:HELPER_SCSI_ error

After a change in the namespace list for a controller, for example the PsaNvmeController, the update semaphore works as expected, but the change might not complete because no lock is available. As a result, the ESXi host fails with a purple diagnostic screen and a `#PF Exception 14 in world 2097479:HELPER_SCSI_ error`.

This issue is resolved in this release.

PR 3267977: You might see spikes in the latency performance metrics after creating a virtual machine disk snapshot

After you create a virtual machine disk snapshot, you might see latency spikes in the vSphere performance charts. Such unusual spikes are due to the recreation of some internal system objects and the restart of the latency performance counters in the storage subsystem.

This issue is resolved in this release. The fix prevents false latency alarms after taking virtual machine disk snapshots.

PR 3305227: If you do not increase the TCP/IP heap memory limit before installation of NSX-T Data Center kernel modules, ESXi hosts might crash

When you install NSX-T Data Center kernel modules on ESXi hosts with high loads, the pre-allocated TCP/IP heap during boot required for the operation might not be sufficient and cause the ESXi host to fail with a purple diagnostic screen. The issue occurs when the TCP/IP heap cannot grow quickly enough to provide a continuous allocation of 2 MB of memory in case of memory fragmentation on such ESXi hosts. As a result, ESXi hosts might fail with a purple diagnostic screen and a `vmkernel.log` error such as

```
Heap: 3707: Heap tcpip (44384680/1073746344): Maximum allowed growth (1048576) too small
for size (1203496)
```

The purple diagnostic screen failure is less likely to occur if you put the ESXi host in maintenance mode before the NSX-T Data Center kernel modules installation, as MM significantly reduces the memory pressure.

This issue is partially resolved in this release. Starting from ESXi 7.0 Update 3, if you are planning an NSX-T Data Center installation, you can increase the `TcpipHeapSize` limit pre-allocated during boot to 128 MB. For example, if you want to increase the `TcpipHeapSize` allocation to the maximum, you can use the following steps:

1. Increase the heap size to 128 MB by using the command `esxcfg-advcfg -s 128 /Net/TcpipHeapSize`

2. Confirm that the heap size is 128 MB: `esxcfg-advcfg -g /Net/TcpipHeapSize`
3. Reboot the ESXi host.

To avoid this issue, you can reboot the ESXi host and install NSX-T Data Center with no VMs running.

PR 3328301: ESXi hosts might fail with a purple diagnostic screen due to a race condition in the High Performance Plug-in (HPP)

Due to a rare race condition in HPP, when a storage path failover and device deletion occur at the same time, ESXi hosts might fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3257098: A virtual machine fails with McastFilter_Deactivate error

In very rare cases, when a VM is low on memory, a code path might not initialize all its members on restart and cause the VM to fail with a purple diagnostic screen and an error such as `McastFilter_Deactivate`.

This issue is resolved in this release. Avoid low memory state of VMs to prevent similar issues.

PR 3317448: IPv6 routing disappears after you deactivate router advertisement on an ESXi host and the host loses connectivity

Deactivating IPv6 router advertisements (RA) on the physical network or deselecting the option "Obtain IP Address through Router Advertisement" at the VMkernel level might cause the default route for the VMkernel adapter to disappear, even when you have a static IPv6 address on the adapter. The issue occurs only when the IPv6 prefix of both the static IP address and the prefix specified in the RA message are the same. As a result, ESXi incorrectly removes the route entry for that particular subnet, despite that the static IP address is still active for the same prefix, and the ESXi host loses connectivity.

This issue is resolved in this release. Avoid using the same IPv6 prefix for both a static IP address and addresses that are automatically configured in RA messages to prevent the issue.

PR 3312843: ESXi hosts intermittently disconnect from the vCenter system and the hostd service restarts

If an ESXi host uses only one of the multipath plug-ins, either HPP or NMP, when the hostd service collects telemetry data on scheduled intervals, the call might return a null pointer value. Dereferencing the `nullptr` might lead to a hostd failure, but the service automatically restarts. As a result, you see the ESXi host intermittently disconnected from the vCenter system.

This issue is resolved in this release. The fix adds a `nullptr` check.

PR 3328337: The hostd service might become unresponsive after a restart due to a rare issue with Inter Process Communication (IPC)

If an IPC process has incorrect payload in the IPC packet, for example: an incorrect version in the header, a deadlock in the iSCSI daemon might cause the hostd service to become unresponsive after a hostd restart. As a result, you cannot perform any operations on the affected ESXi host and VMs by using the vSphere Client.

This issue is resolved in this release.

PR 3285491: You cannot use host profiles to configure a path selection policy for disks using Raw Device Mapping

In some cases, when you try to change or configure the path selection policy of multiple virtual machines by using a host profile, the operation fails for VMs using Raw Device Mapping.

This issue is resolved in this release.

PR 3296093:ESXi hosts intermittently fail with a purple diagnostic screen and a PF Exception 14 error

While running an ESXi upgrade, a rare race condition in the device registration during disk initialization might lead to an ESXi host failing with a purple diagnostic screen. In the screen, you see an error such as `@BlueScreen: #PF`

`Exception 14 in world XXXXX:HELPER_SCSI_ IP` and in the backtrace, you see `vmk_ScsiGetDeviceState` and `nmp_DeviceUpdatePathStates`.

This issue is resolved in this release.

PR 3321157: You might see network outages in vSphere systems using Intel i40en physical NICs and with Enhanced data path enabled

On Intel i40en NICs, TSO packets that exceed the Maximum Segment Size (MSS) of 8 segments might cause the NIC to become unresponsive. In rare cases, a TSO packet from a VM or from a vmknic might exceed the 8-segement limit and you might see network outages due to blocked pNIC tx traffic. The issue is more likely to occur in vSphere systems using Intel i40en physical NICs and with Enhanced data path enabled.

This issue is resolved in this release.

PR 3307580: Large TCP segmentation offload (TSO) packets might cause network traffic latency and intermittent loss of connectivity for some virtual machines

Environments with the enhanced data path networking stack mode enabled might see network traffic latency and intermittent loss of connectivity for some virtual machines due to an issue with the handling of large TSO packets.

This issue is resolved in this release.

PR 3275137: Rare data corruption issue in vSphere systems that use service insertion might lead to ESXi host failure

In vSphere systems that use service insertion, an error with the check of the available buffer size before pulling data might lead to data corruption that might cause the ESXi host to fail with a purple diagnostic screen.

This issue is resolved in this release. The fix makes sure that data pull during service insertion runs only if a sufficient buffer exists.

PR 3270210: The Busybox shell on an ESXi host might fail after you disable echo mode

If you enter a command after `stty -echo`, which disables the echo mode on a Busybox sh shell on an ESXi host, the shell might fail with a coredump.

This issue is resolved in this release.

PR 3319535: Virtual machines with independent_nonpersistent disks might become inaccessible after a VM reset

During a reset, a virtual machine with independent_nonpersistent disks deletes existing redo log files and creates a new redo log. The vmx process updates the new .redo settings in-memory, not in the .vmx file, and when the hostd service reads the disk properties from the .vmx file during sync up, it might consider the redo logs inconsistent. As a result, hostd marks the VM as invalid and the VM becomes inaccessible.

This issue is resolved in this release.

PR 3317445: Enhanced Network Datapath (EDP) might reserve too much memory on a large vSphere system and cause resource issues

EDP reservation is linear to the total memory by reserving up to 1.6% of the total. For a VM with high memory reservation in a large vSphere system, such a memory buffer might be too big. For example, if the system has a 100TB of memory, the EDP reservation might be 1.6TB. As a result, you might see resource issues such as not being able to hot-add VNICs to VMs with high memory reservation.

This issue is resolved in this release. The fix sets the EDP reservation limit at 1% of the total memory and puts a 5GB cap on a single memory reservation. You can adjust the memory reservation limit by using the VMKernel boot option `ensMbufPoolMaxMinMB` or by using the following command: `esxcli system settings kernel set -s ensMbufPoolMaxMBPerGB -v <value-in-MB>`. In any case, you must reboot the ESXi host to enable the change.

PR 3283501: SFCB start, stop, and reporting operations fail due to a stale lockfile: /var/run/sfcbd-init.lock

In rare cases, the `sfcbd-init` script, which creates a lockfile `/var/run/sfcbd-init.lock` to prevent multiple instances of the script from running at the same time, receives a SIGPIPE signal, which terminates the script and leaves the lockfile unhandled. As a result, any further attempts to run the script fail because they cannot acquire the lock.

This issue is resolved in this release. The fix adds SIGPIPE to the list of signals handled by the trap command in the `sfcbd-init` script. This ensures that the lock file is cleared even when the script receives a SIGPIPE signal.

PR 3285243: If an NFS server sends a file handle with 0 length during a new directory creation, ESXi hosts might fail with a purple diagnostic screen

On volumes mounted by using NFSv4.1, if the NFS server sends a file handle with length of 0 in response to a new directory request, the ESXi host might fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3317088: You see slow response times in vSphere environments with NVMe SSDs

When a NVMe SSD fails, it does not respond to any commands from the NVMe driver, such as closing outstanding I/Os. As a result, many I/O and NVMe driver commands might remain pending and cause slow response times in the vSphere environment or even failure of upper layer applications.

This issue is resolved in this release. With the fix, the NVMe driver initiates controller or queue reset in case driver commands are not effective, to allow closing of outstanding I/Os.

PR 3302202: You might see placeholders listed in the Guest OS version drop-down menu for new ESXi virtual machines

When creating a new virtual machine, in the **Guest OS version** drop-down menu you might see placeholders such as Windows 12 and Windows Server 2025. You cannot use such placeholders to create new virtual machines.

This issue is resolved in this release.

PR 3289669: You cannot power on a virtual machine after a failed or canceled export of an Open Virtual Format (OVF) file

A rare deadlock caused by a failed or canceled export of a VM as an OVF file might prevent subsequent start of that VM. The VM appears in a **VM_STATE_EXPORTING** state.

This issue is resolved in this release. If the export of an OVF file fails due to a network outage, you cannot prevent the issue, but you can avoid it if you do not manually cancel OVF exports. If you already face the issue, restart the hostd service on the affected ESXi host by either using the SSH command `/etc/init.d/hostd restart` or selecting **Restart Management Agents** under **Troubleshooting options** in the Direct Console User Interface. The restart of the host service stops any operations on the ESXi host.

PR 3313882: Virtual machines and data objects might become inaccessible after an ESXi firewall refresh

In some scenarios, a refresh of the ESXi firewall on vSAN clusters might refer to an incomplete object in the ESXi Configuration Store (ConfigStore) and cause the Reliable Datagram Transport (RDT) and Cluster Monitoring, Membership and Directory Service (CMMDS) firewall rules to be disabled. As a result, some clusters might be isolated and virtual machines and data objects might become inaccessible.

This issue is resolved in this release.

PR 3280714: In the web console of Linux virtual machines, the Caps Lock option does not work consistently

When you enable the Caps Lock option in the web console of a Linux virtual machine, the typing output might not consistently be capital letters.

This issue is resolved in this release.

PR 3287440: ESXi hosts stop responding to tasks from the vSphere Client

Due to a rare race condition with accessing vSphere Distributed Switch data from competing services, ESXi hosts might stop responding to tasks from the vSphere Client. For example, in NSX Data Center for vSphere environments, you might see an error such as `TN Profile attachment to the cluster is in progress` that prevents you from running other tasks.

This issue is resolved in this release.

PR 3282224: VXLAN traffic generated from a guest VM to port 4789 fails

ESXi hosts have VXLAN port 8472 enabled by default and not the UDP port 4789, which is the default for NSX 6.2.3 and later. As a result, traffic to VXLAN port 4789 fails.

This issue is resolved in this release. The fix adds port 4789 to the list of VXLAN ports by default.

PR 3260070: ESXi hosts might fail with a purple diagnostic screen due to a NULL pointer reference in a tardisk object

A NULL pointer violation with `VisorFSTarDoIOInt()` in the backtrace might cause ESXi hosts to fail with a purple diagnostic screen. The issue occurs in the following conditions:

1. A vSphere admin manually logs into the host by using SSH
2. Modifies a tardisk file, for example in `/etc` , without re-writing the file completely
3. Performs an upgrade that replaces a VIB containing that specific file
4. The admin or an ESXi service access the modified file

This issue is resolved in this release.

PR 3284133: ESXi hosts in environments with NVMe PCIe devices might temporarily lose connectivity during collection of diagnostic information

When you use the `vm-support` command to collect information about ESXi systems such as network, storage, and vSAN, logs for the telemetry and persistent events of NVMe PCIe controllers are temporally stored in the ramdisk `/tmp` directory. If your system has many NVMe PCIe devices or the log file is large, the ramdisk `/tmp` directory quickly becomes full. As a result, ESXi hosts in environments with NVMe PCIe devices might temporarily lose connectivity until the `vm-support` collection completes.

This issue is resolved in this release. The fix selects the VMFS datastore with the most free space to store `nvme` logs and compresses each log file to save storage space.

PR 3275377: VBS-enabled Windows VMs might intermittently fail with a blue diagnostic screen on ESXi hosts running on AMD processors

Windows virtual machines with virtualization-based security (VBS) enabled might intermittently fail with a blue diagnostic screen on ESXi hosts running on AMD processors. The BSOD has the following signature:

```
SECURE_KERNEL_ERROR (18b)The secure kernel has encountered a fatal error.
Arguments:
Arg1: 000000000000018c
Arg2: 000000000000100b
Arg3: 0000000000000000
Arg4: 000000000000409b
```

This issue is resolved in this release.

PR 3259205: A stateless ESXi host might lose connection to vCenter after a reboot

During the boot of a stateless ESXi host, in very rare situations, the management vmknic might change unexpectedly and change the IP address of the host. As a result, the host disconnects from vCenter. If you apply a host profile, in the vSphere Client you might see an error such as **Host profile apply failed with error: Error: A specified parameter was not correct: SelectVnic.vnic.Specification.NetStackInstanceKey.**

This issue is resolved in this release.

ESXi-7.0U3q-23794027-no-tools

Profile Name	ESXi-7.0U3q-23794027-no-tools
Build	For build information, see Patches Contained in This Release.
Vendor	VMware by Broadcom
Release Date	May 21, 2024
Acceptance Level	PartnerSupported

Related CVE numbers	CVE-2024-22273

This patch updates the following issues:

PR 3318350: The sfcb service might fail and generate multiple dump files

Due to a NULL reference, the sfcbd service might fail. You see multiple dump core files created at `/var/core/sfcb-vmware_bas-zdump.`.

This issue is resolved in this release.

PR 3284149: Messages from the vmw_ahci driver flood the vmkernel log

On some servers, an Advanced Host Controller Interface (AHCI) controller might report an unexpected interrupt signal, Port Connect Change Status, very frequently even if no device is connected. As a result, the vmw_ahci driver sends the following message in the vmkernel log files about 100 times every second:

```
vmw_ahci[000000170]:<0> CompletionBottomHalf:hotplug port status: 40, IPM(0), SPD(0), DET(1)
vmw_ahci[000000170]:<0> CompletionBottomHalf:Port Status Reporting Port Connect Enable: Clearing PxSER-
R.DIAG.x
vmw_ahci[000000170]:<0> CompletionBottomHalf:hotplug port status: 40, IPM(0), SPD(0), DET(0)
vmw_ahci[000000170]:<0> CompletionBottomHalf:Port Status Reporting Port Connect Enable: Clearing PxSERR.DIAG.x
```

This issue is resolved in this release. With the fix, the AHCI controller no longer generates Port Connect Change Status interrupt signals and the driver no longer prints such messages.

PR 3297607: An ESXi host might fail with a purple diagnostic screen while connecting to an NVMe over TCP controller

Due to a rare issue in the nvmetcp driver, an ESXi host might fail with a purple diagnostic screen while connecting to an NVMe over TCP controller. In the backtrace, you see a warning such as `WARNING: NVMFDEV:xxxx Failed to connect controller.`.

This issue is resolved in this release.

PR 3281791: I/Os might fail on a NVMe over TCP controller with data digest enabled

If the data digest field exceeds a single memory buffer, the nvmetcp driver might not be able to read it. As a result, the driver might drop the NVMe over TCP connection and trigger a queue reset. If this situation repeats, I/O errors start to occur, which might cause issues such as NVMe over TCP storage becoming inaccessible or applications failing, or in the worst case, the ESXi host might fail with a purple diagnostic screen. In the vmkernel logs, you can see an error such as `Failed to receive data digest: Failure.`.

This issue is resolved in this release.

PR 3266231: If the Maximum Segment Size (MSS) in a TCP packet is less than 64 bytes, Intel X700 series NICs might drop network connection

Intel X700 series NICs regard TCP packets with MSS less than 64 bytes as malicious. As a result, Intel X700 series NICs might not process the Tx path when a VM tries to send such packets, which breaks network connectivity.

This issue is resolved in this release. The fix makes sure that the Intel i40en driver automatically corrects the MSS to a valid size.

PR 3317598: A disk in a vSAN cluster might fail without an error and cause unresponsiveness or failure of virtual machines in the cluster

In rare cases, if an I/O is stuck due to a hardware of firmware issue on a disk in a vSAN cluster, and a transient error occurs at the same time, a race between the stuck I/O and the transient error handling might cause a deadlock. vSAN does not process any reports on events after the deadlock and you do not receive any notifications. As a result, virtual machines on the cluster of the affected disk become unresponsiveness or fail without logs or warning.

This issue is resolved in this release.

PR 3273653: In vSphere systems using memory cards larger than 64GB, you might see "Unable to allocate SCSI_Command" log messages

If you use physical memory cards larger than 64GB for your vSphere system, whenever the number of VM count increases, you might see errors for the SCSI command slab and heap allocations such as `VSCSI: 590: VSCSI_VmkAccumulateSG failed: Out of memory` or `Unable to allocate SCSI_Command.`

This issue is resolved in this release. The fix applies a scale factor based on the size of the physical memory.

PR 3326739: You do not get debugging logs when the vmkdevmgr service fails

In very rare cases, if the vmkdevmgr service fails and core dumps are not enabled, you might not get debugging logs that help you to identify the underlying issue for the failure.

This issue is resolved in this release. The fix adds an automatic check if core dumps for the vmkdevmgr service are enabled.

PR 3309601: The vSphere Virtual Volumes service might fail with a dump while applying a VM Policy to a VM on an ESXi host

In the rare case when an untracked reference to a vendor provider parameter in a vSphere API for Storage Awareness (VASA) session is accessed after deletion, it might cause dump generation. As a result, the vSphere Virtual Volumes service might fail with a dump while applying a VM Policy to a VM on an ESXi host.

This issue is resolved in this release.

PR 3265330: The VMX service might fail during migration of virtual machines with vSphere Virtual Volumes if the volume closure on the source takes long

In some scenarios, such as virtual machines with vSphere Virtual Volumes and Changed Block Tracking (CBT) or Content Based Read Cache (CBRC) enabled, during storage migration, flushing pending I/Os on volume closure at the source might take long, like 10 sec. If clearing the pending I/Os is not complete by the time the VMX service tries to reach the volumes on the destinations host, the service fails.

This issue is resolved in this release. The fix makes sure that all vSphere Virtual Volumes and disks are closed on the source host before the destination host tries to open them.

PR 3331375: Path to SATA drives might move to permanently lost state during a secure wipe operation

During a secure wipe operation, some SATA drives might not provide proper vital product data (VPD) to queries from the host. As a result, the HPP plug-in might incorrectly interpret changes in the physical media and mark a path for the SATA device as permanently lost.

This issue is resolved in this release.

PR 3328638: An ESXi host might fail with a purple diagnostic screen when probe I/Os fail with a retriable error for a long time

In rare scenarios, if for a long period an adapter or device continues to retry an operation that has failed due to a short-lived disruption such as a transient device error or controller reset, a CPU lockup might occur. As a result, an ESXi host might fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3293469: In the vSphere Client, you see a flat line in the read/write IO latency stats for a vSphere Virtual Volumes datastore

In the vSphere Client, when you navigate to **Monitor >Advanced >Datastore** to see the advanced performance metrics of a virtual machine, you might see a flat line in the read/write I/O latency stats for a vSphere Virtual Volumes datastore. The issue occurs due to incorrect calculation of the counters for the read/write I/O latency as a cumulative average.

This issue is resolved in this release.

PR 3303842: WRITE SAME (16) commands with the unmap bit set fail on thick disks

If information from the VPD Page B2 does not prevent the guest OS from activating the unmap bit in a `WRITE SAME (16)` command on thick disks, the command expectedly fails in a vSphere environment. In addition, if the guest OS does not receive a proper error code, it keeps issuing unmap requests by using `WRITE SAME (16)` , also called block zeroing, and this causes I/O errors.

This issue is resolved in this release. With the fix, VPD Page B2 returns proper reports for `WRITE SAME (16)` with unmap support and the guest OS receives a proper error code when unmap is not supported, to prevent unnecessary unmap attempts by the guest.

PR 3314400: An ESXi host fails with a purple diagnostic screen and message @BlueScreen: NMI IPI: Panic requested by another PCPU

In vSphere environments with NSX Data Center, an additional sanity check of the vmxnet3 driver might cause a port or portset lock that might lead to a lock contention. As a result, an ESXi host might fail with a purple diagnostic screen and message `@BlueScreen: NMI IPI: Panic requested by another PCPU.`

This issue is resolved in this release. The fix removes the unnecessary vmxnet3 driver check.

PR 3346924: Upgrade of VMware NSX fails due to a stale DVSPORT_FLAG_RESERVED flag

In very rare cases, a failed vSphere vMotion task might keep a `DVSPORT_FLAG_RESERVED` flag on a port and prevent upgrades of VMware NSX, because the switch on which the port resides cannot be removed. Only a restart of the ESXi host can clean the flag.

This issue is resolved in this release.

PR 3243360: You do not see ESXi host names in the Integrated Dell Remote Access Controller (iDRAC)

When you run the command `localcli hardware ipmi bmc get` in an iDRAC environment, some of the fields for ESXi host names are empty.

This issue is resolved in this release. The fix updates the IPMI BMC hostname during static IP configuration, when the ESXi host is statically configured and rebooted.

PR 3289605: Deactivated transmit queuing option might prevent you from optimizing networking performance

If the `NetSchedHClkVnicMQ` advanced option for transmit queuing is not active, a VNIC with multiple queues might not be able to utilize all queues and prevent significant enhancement of the throughput.

This issue is resolved in this release. The fix makes the `NetSchedHClkVnicMQ` option active by default.

PR 3346935: Migration of virtual machines might fail when vSphere Network I/O Control is active on an ESXi host port to which container ports are mapped to

In rare cases, migrating virtual machines might fail when vSphere Network I/O Control is active on an ESXi host port to which container ports are mapped to, because a dummy port is created at the destination host.

This issue is resolved in this release.

PR 3301661: An I/O filter provider might show offline because of IOFilterVP memory leak

Due to a memory leak in IOFilterVP, an I/O filter provider for an ESXi host might show offline in the vSphere Client under **Configure** > **Storage**. The issue occurs because the SSL cache might consume all heap memory to process VASA API requests.

This issue is resolved in this release. The fix adds a timeout for SSL caching sessions to prevent the memory leak.

PR 3346816: You cannot update the VIB for the NVIDIA GRID vGPU graphics card without rebooting the ESXi host

In case the VIB for the NVIDIA GRID vGPU graphics card is large, lack of sufficient space allocated for the kernel module might prevent automatic update and the operation requires a manual reboot of the ESXi host to complete.

This issue is resolved in this release.

PR 3309482: vSAN host fails with purple diagnostic screen during reboot or mounting a vSAN disk group

A rare issue might cause an incorrect initialization of an internal attribute of a component during recovery of the vSAN logical log, LLOG. As a result, the vSAN host might fail with purple diagnostic screen and in the logs you see an error such as:

```
VMK_ASSERT(cfDisableAssert || LSNEntryLessThan(entry, cfParams->gcpEntry))
```

This issue is resolved in this release.

PR 3306033: You need to manually open the firewall at ports that are different from the default 514 for TCP/UDP and 1514 for SSL protocols

Starting with ESXi 7.0 Update 3q, when you configure syslog remote hosts, or loghosts, with non-standard ports, the vmsyslogd service automatically creates persistent dynamic firewall rules. You no longer need to manually open the firewall at ports that are different from the default 514 for TCP/UDP and 1514 for SSL protocols respectively. When configuring remote hosts with the standard ports, you still need to enable the syslog firewall ruleset.

This issue is resolved in this release. For more information, see Opening the firewall for syslog emission to remote hosts.

PR 3282267: The hostd service might intermittently fail due to an invalid sensor data record

In rare cases, the Baseboard Management Controller (BMC) might provide an invalid sensor data record to the hostd service and cause it to fail. As a result, ESXi hosts become unresponsive or disconnect from vCenter.

This issue is resolved in this release. The fix implements checks to validate the sensor data record before passing it to the hostd service.

PR 3237506: What If analysis on vSAN Capacity screen shows incorrect values when using RAID5 or RAID6 storage policy

In vSAN cluster **Capacity** screen, the What If analysis might show incorrect free space when the cluster is using a RAID5 or RAID6 storage policy.

This issue is resolved in this release.

PR 3276174: vSphere vMotion operations between ESXi 7.x hosts fail with the error "Destination failed to preopen disks"

If on an ESXi 7.x host you use an older Virtual Volumes storage provider, also called a VASA provider, it might not allow binding multiple vSphere Virtual Volumes in batches to optimize the performance of migration and power on. As a result, in the vSphere Client you might see the error `Destination failed to preopen disks` when running vSphere vMotion operations between 7.x hosts.

This issue is resolved in this release.

PR 3311831: ESXi hosts intermittently fail with a purple diagnostic screen and the error "Spin count exceeded - possible deadlock"

Due to a rare issue with packets that might be out of order in a TCP connection, you might see ESXi hosts intermittently to fail with a purple diagnostic screen and the error `Spin count exceeded - possible deadlock.` In the `vmkernel.log` file, you see a backtrace for errors in the tcpip stack such as:

```

This issue is resolved in this release.

PR 3252235: ESXi hosts might fail to boot due to a rare deadlock between open and rename operations on objects with parent-child relationship

A rename operation locks the source and destination directories based on the object pointer address with the assumption that the parent object has the lower address. In rare cases, the assumption might not be correct and the rename lock can happen for the child first and then the parent, while the open operation locks the parent first and then the child. As a result, a deadlock between the open and rename operations occurs and ESXi hosts fail to boot.

This issue is resolved in this release.

PR 3313970: ESXi hosts might fail with a purple diagnostic screen due to a write lock of the uplink watchdog

During a regular sanity check, the uplink watchdog might hold a write lock that prevents reads from other services and might cause the ESXi host might fail with a purple diagnostic screen. In the backtrace, you see errors such as:

```
Panic Message: @BlueScreen: NMI IPI: Panic requested by another PCPU. RIPOFF(base):RBP:CS

[0x14e1e0(0x420033000000):0x430201d03440:0xf48] (Src 0x4, CPU14).
```

This issue is resolved in this release. The fix replaces the write lock with a read lock for regular sanity checks.

PR 3331539: Migration between NSX segments with many container logical ports might cause an ESXi host to fail with a purple diagnostic screen

A rare race condition between vSphere vMotion tasks on NSX Segments with many container logical ports might cause an ESXi host to fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3240662: Host Profile compliance check throws incorrect error message "IPv4 vmknic gateway configuration doesn't match the specification"

In the vSphere Client, you might see the error `IPv4 vmknic gateway configuration doesn't match the specification` when running a compliance check on a Host Profile. The error remains even when you remediate the Host Profile. However, the default gateway settings are defined from the Host Customization workflows and you should not see such an error message during compliance checks. Disregard the message, as it does not affect the host profile functions.

This issue is resolved in this release.

PR 3271089: Virtual machines with a lightweight delta (LWD) snapshot might fail to start after a failure of the vmx service

In rare cases, if the vmx service fails during the creation of a LWD snapshot, some partially initialized LWD snapshot files might remain on the datastore. As a result, virtual machines with such LWD snapshots might fail to start due to validation failures.

This issue is resolved in this release.

PR 3304469: vSphere vMotion operations might fail due to a rare issue with no namespaces present in the namespacemgr.db file

When a virtual machine is configured with namespaces and for some reason the namespaces table in the `namespacemgr.db` file is empty in the ESXi host database, migration of such a VM by using vSphere vMotion might fail. In the `vmware.log` file, you see errors such as:

```
vmx - NamespaceMgrCheckpoint: No valid queue found while restoring the namespace events.
The migrate type is 1.
```

This issue is resolved in this release.

PR 3291105: While detaching an Enhanced Networking Stack (ENS) port from an ESXi host, the host might fail with a purple diagnostic screen

During deactivation of ENS in scenarios such as an upgrade or a VNIC configuration change, while detaching an ENS port from an ESXi host with active ENS, the port might be removed from the port list and not be available for further reference, which might cause an invalid memory access error. As a result, the ESXi host fails with a purple diagnostic screen.

This issue is resolved in this release.

PR 3346938: After a NSX Distributed Security installation, vSphere vMotion might not restore a switch security filter on the destination side

When you opt to install the Security Only option of NSX Distributed Security, vSphere vMotion might not restore a switch security filter on the destination side and the Address Resolution Protocol (ARP) fails.

This issue is resolved in this release.

PR 3312150: Failover of VMs on vSphere Virtual Volume datastores might fail due to wrong order of metadata from vSphere API for Storage Awareness (VASA) provider

Certain VASA providers might return metadata info in a different order than what an ESXi host requests. As a result, when VMs on a vSphere Virtual Volume datastore fail over to a recovery site, the VMs cannot reboot on the target site.

This issue is resolved in this release. With the fix, even if a VASA provider returns metadata info in a different order from the ESXi host request, failover succeeds.

PR 3328641: An ESXi host might fail with a purple diagnostic screen due to a rare issue during a read-modify-write (RMW) operation

On 512e software emulated devices, when I/O requests are not multiple of 4096, ESXi runs RMW operations. In such cases, the final write I/O issue path can access the write command frame after the write is issued to the target. If the target completes the write request before the issue path accesses the write frame, the write frame is freed. As a result, you might see a Use-After-Free scenario that might lead to failure of the ESXi host with a purple diagnostic screen.

This issue is resolved in this release.

PR 3332098: Asynchronous write operations to a SMB file share on the vSAN File Service might cause data transfer issues

In rare cases, a race condition during asynchronous write operations to a SMB file share on the vSAN File Service might cause data transfer issues such as truncation.

This issue is resolved in this release.

PR 3256992: vSphere vMotion tasks fail for VMs on port groups with promiscuous mode enabled

A rare issue with corrupted network packets that becomes evident in secure network protocols, where packet data integrity is checked upon receipt, might lead to connectivity issues on port groups with promiscuous mode enabled. As a result, you might see vSphere vMotion tasks failing for VMs on such port groups. You see data integrity errors such as `Failed to decrypt ciphertext` in the backtrace.

This issue is resolved in this release.

PR 3244429: Exit Code 127 error in the hostd service might cause an ESXi host to disconnect temporarily from vCenter

Due to an issue in the open source glibc components, attempts by hostd to process the list of installed I/O filters on an ESXi host might intermittently cause an Exit Code 127 error. In the `/var/run/log/syslog.log` , you see lines such as:

```
2022-10-13T08:00:20.180Z watchdog-hostd[<PID>]: 'hostd ++min=0,swapscope=system' exited after X seconds 127
```

As a result, the ESXi host temporarily disconnects from vCenter until the hostd watchdog restarts the service and connectivity restores. The issue has been observed while loading the `vmwarelwd` I/O filter.

This issue is resolved in this release. ESXi 7.0 Update 3q adds a hostd configuration option that allows you to deactivate an I/O filter without removing it from the vCenter system and skip reporting such filters in the host configuration overhead. To use the option, log in to SSH and complete the following steps:

1. Set the `plugins/hostsvc/report_disabled_filters_in_host_config` option in the hostd configuration to `False` as described in VMware knowledge base article 82227.
2. Deactivate the `vmwarelwd` filter by running the following python script directly on the host:

   ```
   import vmware.vsi as vsi
   vsi.set('/iofilters/statusDisabledEvent', {'filterName': 'vmwarelwd', 'failureReason' : 'workaround'})
   ```

PR 3332691: vSAN IOPS performance data not available for VM multi-writer virtual disk

The following performance charts for a vSAN VM multi-writer virtual disk, under **Monitor** > **vSAN** > **Performance** > **Virtual Disks**, are not available: IOPS, IOPS limit, and Delayed Normalized IOPS. These charts are available only for disks without active multi-writer mode.

This issue is resolved in this release.

PR 3288607: An ESXi host might fail with a purple diagnostic screen due to a rare storage heap corruption in NVMe devices

In rare cases, an I/O thread from a NVMe device, such as deleting a virtual machine from a datastore using NVMe devices, might complete before the High-Performance Plug-in (HPP) claims the device to complete the thread. As a result, HPP tries to access a non-existing thread which leads to a failure of the ESXi host with a purple diagnostic screen and an error such as `PSOD @BlueScreen: PANIC bora/vmkernel/main/dlmalloc.c:4763` .

This issue is resolved in this release.

PR 3273752: ESXi hosts fail with a purple diagnostic screen and a #PF Exception 14 in world 2097479:HELPER_SCSI_ error

After a change in the namespace list for a controller, for example the PsaNvmeController, the update semaphore works as expected, but the change might not complete because no lock is available. As a result, the ESXi host fails with a purple diagnostic screen and a `#PF Exception 14 in world 2097479:HELPER_SCSI_ error` .

This issue is resolved in this release.

PR 3267977: You might see spikes in the latency performance metrics after creating a virtual machine disk snapshot

After you create a virtual machine disk snapshot, you might see latency spikes in the vSphere performance charts. Such unusual spikes are due to the recreation of some internal system objects and the restart of the latency performance counters in the storage subsystem.

This issue is resolved in this release. The fix prevents false latency alarms after taking virtual machine disk snapshots.

PR 3305227: If you do not increase the TCP/IP heap memory limit before installation of NSX-T Data Center kernel modules, ESXi hosts might crash

When you install NSX-T Data Center kernel modules on ESXi hosts with high loads, the pre-allocated TCP/IP heap during boot required for the operation might not be sufficient and cause the ESXi host to fail with a purple diagnostic screen. The issue occurs when the TCP/IP heap cannot grow quickly enough to provide a continuous allocation of 2 MB of memory in case of memory fragmentation on such ESXi hosts. As a result, ESXi hosts might fail with a purple diagnostic screen and a `vmkernel.log` error such as

```
Heap: 3707: Heap tcpip (44384680/1073746344): Maximum allowed growth (1048576) too small for size (1203496)
```

The purple diagnostic screen failure is less likely to occur if you put the ESXi host in maintenance mode before the NSX-T Data Center kernel modules installation, as MM significantly reduces the memory pressure.

This issue is partially resolved in this release. Starting from ESXi 7.0 Update 3, if you are planning an NSX-T Data Center installation, you can increase the `TcpipHeapSize` limit pre-allocated during boot to 128 MB. For example, if you want to increase the `TcpipHeapSize` allocation to the maximum, you can use the following steps:

1. Increase the heap size to 128 MB by using the command `esxcfg-advcfg -s 128 /Net/TcpipHeapSize`
2. Confirm that the heap size is 128 MB: `esxcfg-advcfg -g /Net/TcpipHeapSize`
3. Reboot the ESXi host.

To avoid this issue, you can reboot the ESXi host and install NSX-T Data Center with no VMs running.

PR 3328301: ESXi hosts might fail with a purple diagnostic screen due to a race condition in the High Performance Plug-in (HPP)

Due to a rare race condition in HPP, when a storage path failover and device deletion occur at the same time, ESXi hosts might fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3257098: A virtual machine fails with McastFilter_Deactivate error

In very rare cases, when a VM is low on memory, a code path might not initialize all its members on restart and cause the VM to fail with a purple diagnostic screen and an error such as `McastFilter_Deactivate`.

This issue is resolved in this release. Avoid low memory state of VMs to prevent similar issues.

PR 3317448: IPv6 routing disappears after you deactivate router advertisement on an ESXi host and the host loses connectivity

Deactivating IPv6 router advertisements (RA) on the physical network or deselecting the option "Obtain IP Address through Router Advertisement" at the VMkernel level might cause the default route for the VMkernel adapter to disappear, even when you have a static IPv6 address on the adapter. The issue occurs only when the IPv6 prefix of both the static IP address and the prefix specified in the RA message are the same. As a result, ESXi incorrectly removes the route entry for that particular subnet, despite that the static IP address is still active for the same prefix, and the ESXi host loses connectivity.

This issue is resolved in this release. Avoid using the same IPv6 prefix for both a static IP address and addresses that are automatically configured in RA messages to prevent the issue.

PR 3312843: ESXi hosts intermittently disconnect from the vCenter system and the hostd service restarts

If an ESXi host uses only one of the multipath plug-ins, either HPP or NMP, when the hostd service collects telemetry data on scheduled intervals, the call might return a null pointer value. Dereferencing the `nullptr` might lead to a hostd failure, but the service automatically restarts. As a result, you see the ESXi host intermittently disconnected from the vCenter system.

This issue is resolved in this release. The fix adds a `nullptr` check.

PR 3328337: The hostd service might become unresponsive after a restart due to a rare issue with Inter Process Communication (IPC)

If an IPC process has incorrect payload in the IPC packet, for example: an incorrect version in the header, a deadlock in the iSCSI daemon might cause the hostd service to become unresponsive after a hostd restart. As a result, you cannot perform any operations on the affected ESXi host and VMs by using the vSphere Client.

This issue is resolved in this release.

PR 3285491: You cannot use host profiles to configure a path selection policy for disks using Raw Device Mapping

In some cases, when you try to change or configure the path selection policy of multiple virtual machines by using a host profile, the operation fails for VMs using Raw Device Mapping.

This issue is resolved in this release.

PR 3296093:ESXi hosts intermittently fail with a purple diagnostic screen and a PF Exception 14 error

While running an ESXi upgrade, a rare race condition in the device registration during disk initialization might lead to an ESXi host failing with a purple diagnostic screen. In the screen, you see an error such as `@BlueScreen: #PF Exception 14 in world XXXXX:HELPER_SCSI_ IP` and in the backtrace, you see `vmk_ScsiGetDeviceState` and `nmp_DeviceUpdatePathStates`.

This issue is resolved in this release.

PR 3321157: You might see network outages in vSphere systems using Intel i40en physical NICs and with Enhanced data path enabled

On Intel i40en NICs, TSO packets that exceed the Maximum Segment Size (MSS) of 8 segments might cause the NIC to become unresponsive. In rare cases, a TSO packet from a VM or from a vmknic might exceed the 8-segement limit and you might see network outages due to blocked pNIC tx traffic. The issue is more likely to occur in vSphere systems using Intel i40en physical NICs and with Enhanced data path enabled.

This issue is resolved in this release.

PR 3307580: Large TCP segmentation offload (TSO) packets might cause network traffic latency and intermittent loss of connectivity for some virtual machines

Environments with the enhanced data path networking stack mode enabled might see network traffic latency and intermittent loss of connectivity for some virtual machines due to an issue with the handling of large TSO packets.

This issue is resolved in this release.

PR 3275137: Rare data corruption issue in vSphere systems that use service insertion might lead to ESXi host failure

In vSphere systems that use service insertion, an error with the check of the available buffer size before pulling data might lead to data corruption that might cause the ESXi host to fail with a purple diagnostic screen.

This issue is resolved in this release. The fix makes sure that data pull during service insertion runs only if a sufficient buffer exists.

PR 3270210: The Busybox shell on an ESXi host might fail after you disable echo mode

If you enter a command after `stty -echo`, which disables the echo mode on a Busybox sh shell on an ESXi host, the shell might fail with a coredump.

This issue is resolved in this release.

PR 3319535: Virtual machines with independent_nonpersistent disks might become inaccessible after a VM reset

During a reset, a virtual machine with independent_nonpersistent disks deletes existing redo log files and creates a new redo log. The vmx process updates the new .redo settings in-memory, not in the .vmx file, and when the hostd service reads the disk properties from the .vmx file during sync up, it might consider the redo logs inconsistent. As a result, hostd marks the VM as invalid and the VM becomes inaccessible.

This issue is resolved in this release.

PR 3317445: Enhanced Network Datapath (EDP) might reserve too much memory on a large vSphere system and cause resource issues

EDP reservation is linear to the total memory by reserving up to 1.6% of the total. For a VM with high memory reservation in a large vSphere system, such a memory buffer might be too big. For example, if the system has a 100TB of memory, the EDP reservation might be 1.6TB. As a result, you might see resource issues such as not being able to hot-add VNICs to VMs with high memory reservation.

This issue is resolved in this release. The fix sets the EDP reservation limit at 1% of the total memory and puts a 5GB cap on a single memory reservation. You can adjust the memory reservation limit by using the VMKernel boot option `ensMbufPoolMaxMinMB` or by using the following command: `esxcli system settings kernel set -s ensMbufPoolMaxMBPerGB -v <value-in-MB>`. In any case, you must reboot the ESXi host to enable the change.

PR 3283501: SFCB start, stop, and reporting operations fail due to a stale lockfile: /var/run/sfcbd-init.lock

In rare cases, the `sfcbd-init` script, which creates a lockfile `/var/run/sfcbd-init.lock` to prevent multiple instances of the script from running at the same time, receives a SIGPIPE signal, which terminates the script and leaves the lockfile unhandled. As a result, any further attempts to run the script fail because they cannot acquire the lock.

This issue is resolved in this release. The fix adds SIGPIPE to the list of signals handled by the trap command in the `sfcbd-init` script. This ensures that the lock file is cleared even when the script receives a SIGPIPE signal.

PR 3285243: If an NFS server sends a file handle with 0 length during a new directory creation, ESXi hosts might fail with a purple diagnostic screen

On volumes mounted by using NFSv4.1, if the NFS server sends a file handle with length of 0 in response to a new directory request, the ESXi host might fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3317088: You see slow response times in vSphere environments with NVMe SSDs

When a NVMe SSD fails, it does not respond to any commands from the NVMe driver, such as closing outstanding I/Os. As a result, many I/O and NVMe driver commands might remain pending and cause slow response times in the vSphere environment or even failure of upper layer applications.

This issue is resolved in this release. With the fix, the NVMe driver initiates controller or queue reset in case driver commands are not effective, to allow closing of outstanding I/Os.

PR 3302202: You might see placeholders listed in the Guest OS version drop-down menu for new ESXi virtual machines

When creating a new virtual machine, in the **Guest OS version** drop-down menu you might see placeholders such as Windows 12 and Windows Server 2025. You cannot use such placeholders to create new virtual machines.

This issue is resolved in this release.

PR 3289669: You cannot power on a virtual machine after a failed or canceled export of an Open Virtual Format (OVF) file

A rare deadlock caused by a failed or canceled export of a VM as an OVF file might prevent subsequent start of that VM. The VM appears in a **VM_STATE_EXPORTING** state.

This issue is resolved in this release. If the export of an OVF file fails due to a network outage, you cannot prevent the issue, but you can avoid it if you do not manually cancel OVF exports. If you already face the issue, restart the hostd service on the affected ESXi host by either using the SSH command `/etc/init.d/hostd restart` or selecting **Restart Management Agents** under **Troubleshooting options** in the Direct Console User Interface. The restart of the host service stops any operations on the ESXi host.

PR 3313882: Virtual machines and data objects might become inaccessible after an ESXi firewall refresh

In some scenarios, a refresh of the ESXi firewall on vSAN clusters might refer to an incomplete object in the ESXi Configuration Store (ConfigStore) and cause the Reliable Datagram Transport (RDT) and Cluster Monitoring, Membership and Directory Service (CMMDS) firewall rules to be disabled. As a result, some clusters might be isolated and virtual machines and data objects might become inaccessible.

This issue is resolved in this release.

PR 3280714: In the web console of Linux virtual machines, the Caps Lock option does not work consistently

When you enable the Caps Lock option in the web console of a Linux virtual machine, the typing output might not consistently be capital letters.

This issue is resolved in this release.

PR 3287440: ESXi hosts stop responding to tasks from the vSphere Client

Due to a rare race condition with accessing vSphere Distributed Switch data from competing services, ESXi hosts might stop responding to tasks from the vSphere Client. For example, in NSX Data Center for vSphere environments, you might see an error such as `TN Profile attachment to the cluster is in progress` that prevents you from running other tasks.

This issue is resolved in this release.

PR 3282224: VXLAN traffic generated from a guest VM to port 4789 fails

ESXi hosts have VXLAN port 8472 enabled by default and not the UDP port 4789, which is the default for NSX 6.2.3 and later. As a result, traffic to VXLAN port 4789 fails.

This issue is resolved in this release. The fix adds port 4789 to the list of VXLAN ports by default.

PR 3260070: ESXi hosts might fail with a purple diagnostic screen due to a NULL pointer reference in a tardisk object

A NULL pointer violation with `VisorFSTarDoIOInt()` in the backtrace might cause ESXi hosts to fail with a purple diagnostic screen. The issue occurs in the following conditions:

1. A vSphere admin manually logs into the host by using SSH
2. Modifies a tardisk file, for example in `/etc` , without re-writing the file completely
3. Performs an upgrade that replaces a VIB containing that specific file
4. The admin or an ESXi service access the modified file

This issue is resolved in this release.

PR 3284133: ESXi hosts in environments with NVMe PCIe devices might temporarily lose connectivity during collection of diagnostic information

When you use the `vm-support` command to collect information about ESXi systems such as network, storage, and vSAN, logs for the telemetry and persistent events of NVMe PCIe controllers are temporally stored in the ramdisk `/tmp` directory. If your system has many NVMe PCIe devices or the log file is large, the ramdisk `/tmp` directory quickly becomes full. As a result, ESXi hosts in environments with NVMe PCIe devices might temporarily lose connectivity until the `vm-support` collection completes.

This issue is resolved in this release. The fix selects the VMFS datastore with the most free space to store `nvme` logs and compresses each log file to save storage space.

PR 3275377: VBS-enabled Windows VMs might intermittently fail with a blue diagnostic screen on ESXi hosts running on AMD processors

Windows virtual machines with virtualization-based security (VBS) enabled might intermittently fail with a blue diagnostic screen on ESXi hosts running on AMD processors. The BSOD has the following signature:

```
SECURE_KERNEL_ERROR (18b)The secure kernel has encountered a fatal error.
Arguments:
Arg1: 000000000000018c
Arg2: 000000000000100b
Arg3: 0000000000000000
Arg4: 000000000000409b
```

This issue is resolved in this release.

PR 3259205: A stateless ESXi host might lose connection to vCenter after a reboot

During the boot of a stateless ESXi host, in very rare situations, the management vmknic might change unexpectedly and change the IP address of the host. As a result, the host disconnects from vCenter. If you apply a host profile, in the vSphere Client you might see an error such as **Host profile apply failed with error: Error: A specified parameter was not correct: SelectVnic.vnic.Specification.NetStackInstanceKey.**

This issue is resolved in this release.

VMware Tools Bundling Changes in ESXi 7.0 Update 3q

The following VMware Tools ISO images are bundled with ESXi 7.0 Update 3q:

- **windows.iso**: VMware Tools 12.3.5 supports Windows 7 SP1 or Windows Server 2008 R2 SP1 and later.
- **linux.iso**: VMware Tools 10.3.26 ISO image for Linux OS with **glibc** 2.11 or later.

The following VMware Tools ISO images are available for download:

- VMware Tools 11.0.6:
  - **windows.iso**: for Windows Vista (SP2) and Windows Server 2008 Service Pack 2 (SP2).
- VMware Tools 10.0.12:
  - **winPreVista.iso**: for Windows 2000, Windows XP, and Windows 2003.
  - **linuxPreGLibc25.iso**: supports Linux guest operating systems earlier than Red Hat Enterprise Linux (RHEL) 5, SUSE Linux Enterprise Server (SLES) 11, Ubuntu 7.04, and other distributions with **glibc** version earlier than 2.5.
- **solaris.iso**: VMware Tools image 10.3.10 for Solaris.
- **darwin.iso**: Supports Mac OS X versions 10.11 and later.

Follow the procedures listed in the following documents to download VMware Tools for platforms not bundled with ESXi:

- VMware Tools 12.3.5 Release Notes
- Earlier versions of VMware Tools
- What Every vSphere Admin Must Know About VMware Tools
- VMware Tools for hosts provisioned with Auto Deploy
- Updating VMware Tools

ESXi 7.0 Update 3q provides the following security updates:

- The Python library is updated to version 3.8.18.
- The zlib library is updated to version 1.3.
- The cURL library is updated to version 8.4.0.
- The c-ares C library is updated to version 1.19.1.

ESXi 7.0 Update 3q includes the following Intel microcode:

ESXi-7.0U3sq-23794019-no-tools

Profile Name	ESXi-7.0U3sq-23794019-no-tools
Build	For build information, see Patches Contained in This Release.
Vendor	VMware by Broadcom
Release Date	May 21, 2024
Acceptance Level	PartnerSupported
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_bootbank_crx_7.0.3-0.120.23794019 • VMware_bootbank_cpu-microcode_7.0.3-0.120.23794019 • VMware_bootbank_gc_7.0.3-0.120.23794019 • VMware_bootbank_esx-xserver_7.0.3-0.120.23794019 • VMware_bootbank_bmcal_7.0.3-0.120.23794019 • VMware_bootbank_vdfs_7.0.3-0.120.23794019 • VMware_bootbank_native-misc-drivers_7.0.3-0.120.23794019 • VMware_bootbank_trx_7.0.3-0.120.23794019 • VMware_bootbank_vsanhealth_7.0.3-0.120.23794019 • VMware_bootbank_esx-base_7.0.3-0.120.23794019 • VMware_bootbank_vsan_7.0.3-0.120.23794019

Related CVE numbers	CVE-2024-22273

This patch updates the following issues:

ESXi 7.0 Update 3q provides the following security updates:

- The Python library is updated to version 3.8.18.
- The zlib library is updated to version 1.3.
- The cURL library is updated to version 8.4.0.
- The c-ares C library is updated to version 1.19.1.

ESXi 7.0 Update 3q includes the following Intel microcode:

ESXi7.0U3q - 23794027

Name	ESXi
Version	ESXi7.0U3q - 23794027
Release Date	May 21, 2024
Category	Bugfix
Affected Components	• ESXi Component - core • ESXi VIBs ESXi Install/Upgrade Component • Network driver for Intel(R) X710/XL710/XXV710/X722 Adapters • VMware Native AHCI Driver
PRs Fixed	3269229, 3336578, 3332098, 3324772, 3337108, 3319535, 3336916, 3331375, 3326805, 3335978, 3267977, 3323978, 3331256, 3332691, 3313970, 3312843, 3309601, 3317598, 3323119, 3326739, 3317618, 3244429, 3328641, 3328638, 3328337, 3326300, 3329238, 3328301, 3297696, 3296093, 3317448, 3285491, 3276174, 3297629, 3314959, 3309482, 3320147, 3297625, 3297729, 3311303, 3297704, 3309472, 3297749, 3298709, 3320949, 3310432, 3297774, 3302255, 3270210, 3311302, 3257098, 3311831, 3309603, 3317088, 3321157, 2964964, 3305227, 3318350, 3256083, 3269969, 3317445, 3314400, 3267704, 2760003, 3313882, 3243360, 3293469, 3284876, 3265330, 3303842, 3303855, 3293093, 3309148, 3307580, 3301661, 3304469, 3260297, 3260070, 3297409, 3252235, 3287748, 3306033, 3273752, 3288607, 3289238, 3284916, 3303694, 3284133, 3273653, 3298508, 3289605, 3289669, 3291198, 3240347, 3280468, 3285518, 3283501, 3275377, 3267449, 3282267, 3256992, 3251790, 3275137, 3240662, 3259035, 3259205, 3266912, 3282224, 3273653, 3346924, 3346935, 3346816, 3237506, 3331539, 3271089, 3291105, 3346938, 3312150, 3284149, 3266231, 3317204, 3297607, 3281791
Related CVE numbers	CVE-2024-22273

This patch resolves the issues listed in ESXi-7.0U3q-23794027-standard.

ESXi7.0U3sq - 23794019

Name	ESXi
Version	ESXi7.0U3sq - 23794019
Release Date	May 21, 2024
Category	Security
Affected Components	• ESXi Component - core ESXi VIBs • ESXi Install/Upgrade Component • ESXi Tools Component

PRs Fixed	3352357, 3340944, 3330942, 3293531, 3368526, 3373896, 3378149, 3331610, 3293308, 3269602, 3293518, 3312311, 3293459, 3293188, 3260854, 3293307, 3302202, 3293541, 3269861, 3296323, 3280714, 3304808, 3293185
Related CVE numbers	CVE-2024-22273

This patch resolves the issues listed in ESXi-7.0U3sq-23794019-standard.

Known Issues

Virtual Machine Management Issues

Compatibility check for assignable hardware might fail even when no external device is in use

In some cases, when you revert a virtual machine with an assignable hardware (AH) device, such as a GPU resource, to a snapshot when the VM did not have the AH device, some stale bindings might remain. As a result, you see compatibility checks on the reverted VM failing with an error such as `InsufficientResourcesFault for pciPassthru0` , even though the GPU resource is no longer attached.

Workaround: To avoid the issue, for ESXi version 7.x, revert virtual machines with AH or passthrough devices only from snapshots you take from powered off VMs. If you already face the issue, restart the hostd service to release stale bindings and start GPU VMs. Alternatively, upgrade your hosts to ESXi version 8.0 or later.

Known Issues from Previous Releases

For a list of known issues from previous releases, see VMware ESXi 7.0 Update 3p Release Notes.

VMware ESXi 7.0 Update 3p Release Notes

This document contains the following sections

- Introduction
- What's New
- Earlier Releases of ESXi 7.0
- Patches Contained in This Release
- Patch Download and Installation
- Resolved Issues
- Known Issues from Previous Releases

Introduction

VMware ESXi 7.0 Update 3p | 11 APR 2024 | Build 23307199 Check for additions and updates to these release notes.

IMPORTANT: If your source system contains hosts of versions between ESXi 7.0 Update 2 and Update 3c, and Intel drivers, before upgrading to ESXi 7.0 Update 3p, see the What's New section of the VMware vCenter Server 7.0 Update 3c Release Notes, because all content in the section is also applicable for vSphere 7.0 Update 3p. Also, see the related VMware knowledge base articles: 86447, 87258, and 87308.

What's New

This release resolves CVE-2024-22252, CVE-2024-22253, CVE-2024-22254, and CVE-2024-22255. For more information on these vulnerabilities and their impact on VMware products, see VMSA-2024-0006.

Earlier Releases of ESXi 7.0

New features, resolved, and known issues of ESXi are described in the release notes for each release. Release notes for earlier releases of ESXi 7.0 are:

- VMware ESXi 7.0, ESXi 7.0 Update 3p Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3o Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3n Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3m Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3l Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3k Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3j Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3i Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3g Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3f Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2a Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2 Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1b Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1a Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1 Release Notes
- VMware ESXi 7.0, ESXi 7.0b Release Notes

For internationalization, compatibility, and open source components, see the VMware vSphere 7.0 Release Notes.

Patches Contained in This Release

This release of ESXi 7.0 Update 3p delivers the following patches:

Build Details

Download Filename:	VMware-ESXi-7.0U3p-23307199-depot.zip
Build:	23307199
Download Size:	381.3 MB
md5sum:	9b04d3fb0cbda95ba2dd06a042971d56
sha256checksum:	f407cf873d191c453ff805b04f75398874bce63120443ce835a2da28977977b1
Host Reboot Required:	Yes
Virtual Machine Migration or Shutdown Required:	Yes

Components

Component	Bulletin	Category	Severity
ESXi Component - core ESXi VIBs	ESXi_7.0.3-0.110.23307199	Security	Critical
ESXi Install/Upgrade Component	esx-update_7.0.3-0.110.23307199	Security	Critical

IMPORTANT:

- Starting with vSphere 7.0, VMware uses components for packaging VIBs along with bulletins. The `ESXi` and `esx-update` bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.
- When patching ESXi hosts by using VMware Update Manager from a version prior to ESXi 7.0 Update 2, it is strongly recommended to use the rollup bulletin in the patch baseline. If you cannot use the rollup bulletin, be sure to include *all* of the following packages in the patching baseline. If the following packages are not included in the baseline, the update operation fails:
  - VMware-vmkusb_0.1-1vmw.701.0.0.16850804 or higher
  - VMware-vmkata_0.1-1vmw.701.0.0.16850804 or higher
  - VMware-vmkfcoe_1.0.0.2-1vmw.701.0.0.16850804 or higher
  - VMware-NVMeoF-RDMA_1.0.1.2-1vmw.701.0.0.16850804 or higher

Rollup Bulletin

This rollup bulletin contains the latest VIBs with all the fixes after the initial release of ESXi 7.0.

Bulletin ID	Category	Severity	Details
ESXi70U3p-23307199	Security	Critical	Security only

Image Profiles

VMware patch and update releases contain general and critical image profiles. Application of the general release image profile applies to new bug fixes.

Image Profile Name
ESXi-7.0U3p-23307199-standard
ESXi-7.0U3p-23307199-no-tools

ESXi Image

Name and Version	Release Date	Category	Details
ESXi7.0U3p - 23307199	MAR 05 2024	Security	Security only image

For information about the individual components and bulletins, see the Resolved Issues section.

Patch Download and Installation

Log in to the Broadcom Support Portal to download this patch.

For download instructions for earlier releases, see Download Broadcom products and software.

In vSphere 7.x, the Update Manager plug-in, used for administering vSphere Update Manager, is replaced with the Lifecycle Manager plug-in. Administrative operations for vSphere Update Manager are still available under the Lifecycle Manager plug-in, along with new capabilities for vSphere Lifecycle Manager.

The typical way to apply patches to ESXi 7.x hosts is by using the vSphere Lifecycle Manager. For details, see About vSphere Lifecycle Manager and vSphere Lifecycle Manager Baselines and Images.

You can also update ESXi hosts without using the Lifecycle Manager plug-in, and use an image profile instead. To do this, you must manually download the patch offline bundle ZIP file.

For details, see Upgrading Hosts by Using ESXCLI Commands, and the VMware ESXi Upgrade guide.

Resolved Issues

The resolved issues are grouped as follows:

ESXi_7.0.3-0.110.23307199

Patch Category	Security
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs Included	• VMware_bootbank_vsan_7.0.3-0.110.23307199 • VMware_bootbank_esxio-combiner_7.0.3-0.110.23307199 • VMware_bootbank_crx_7.0.3-0.110.23307199 • VMware_bootbank_vsanhealth_7.0.3-0.110.23307199 • VMware_bootbank_trx_7.0.3-0.110.23307199 • VMware_bootbank_vdfs_7.0.3-0.110.23307199 • VMware_bootbank_native-misc-drivers_7.0.3-0.110.23307199 • VMware_bootbank_esx-dvfilter-generic-fastpath_7.0.3-0.110.23307199 • VMware_bootbank_bmcal_7.0.3-0.110.23307199 • VMware_bootbank_esx-xserver_7.0.3-0.110.23307199 • VMware_bootbank_esx-base_7.0.3-0.110.23307199 • VMware_bootbank_cpu-microcode_7.0.3-0.110.23307199 • VMware_bootbank_gc_7.0.3-0.110.23307199
PRs Fixed	N/A
CVE numbers	CVE-2024-22252, CVE-2024-22253, CVE-2024-22254, CVE-2024-22255

The ESXi and esx-update bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.

This patch updates the `esx-base` VIB. Due to their dependency with the `esx-base` VIB, the following VIBs are updated with build number and patch version changes, but deliver no fixes: `trx`, `vdfs`, `native-misc-drivers`, `esx-dvfilter-generic-fastpath`, `bmcal`, `esx-xserver`, `esx-base`, `cpu-microcode` , and `gc` . This patch resolves the following issue:

This release resolves CVE-2024-22252, CVE-2024-22253, CVE-2024-22254, and CVE-2024-22255. For more information on these vulnerabilities and their impact on VMware products, see VMSA-2024-0006.

esx-update_7.0.3-0.110.23307199

Patch Category	Security
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_bootbank_loadesx_7.0.3-0.110.23307199 • VMware_bootbank_esx-update_7.0.3-0.110.23307199
PRs Fixed	N/A
CVE numbers	N/A

Due to their dependency on the `esx-base` VIB, the following VIBs are updated with build number and patch version changes, but deliver no fixes: `loadesx` and `esx-update` .

ESXi-7.0U3p-23307199-standard

Profile Name	ESXi-7.0U3p-23307199-standard
Build	For build information, see Patches Contained in This Release.
Vendor	VMware by Broadcom, Inc.
Release Date	March 05, 2024
Acceptance Level	PartnerSupported
Affected Hardware	N/A
Affected Software	N/A

PRs Fixed	N/A
Related CVE numbers	CVE-2024-22252, CVE-2024-22253, CVE-2024-22254, CVE-2024-22255

This patch updates the following issue:

This release resolves CVE-2024-22252, CVE-2024-22253, CVE-2024-22254, and CVE-2024-22255. For more information on these vulnerabilities and their impact on VMware products, see VMSA-2024-0006.

ESXi7.0U3p - 23307199

Name	ESXi
Version	ESXi7.0U3p - 23307199
Release Date	March 05, 2024
Category	Security
Affected Components	• ESXi Component - core ESXi

	• ESXi Install/Upgrade
PRs Fixed	N/A
Related CVE numbers	CVE-2024-22252, CVE-2024-22253, CVE-2024-22254, CVE-2024-22255

This patch resolves the issues listed in ESXi-7.0U3p-23307199-standard.

Known Issues from Previous Releases

vSphere Cluster Services Issues

You see compatibility issues in new vCLS VMs deployed in vSphere 7.0 Update 3 environment

The default name for new vCLS VMs deployed in vSphere 7.0 Update 3 environment uses the pattern vCLS-UUID. vCLS VMs created in earlier vCenter Server versions continue to use the pattern vCLS (n). Since the use of parenthesis () is not supported by many solutions that interoperate with vSphere, you might see compatibility issues.

Workaround: Reconfigure vCLS by using retreat mode after updating to vSphere 7.0 Update 3.

Installation, Upgrade, and Migration Issues

The vCenter Upgrade/Migration pre-checks fail with "Unexpected error 87"

The vCenter Server Upgrade/Migration pre-checks fail when the Security Token Service (STS) certificate does not contain a Subject Alternative Name (SAN) field. This situation occurs when you have replaced the vCenter 5.5 Single Sign-On certificate with a custom certificate that has no SAN field, and you attempt to upgrade to vCenter Server 7.0. The upgrade considers the STS certificate invalid and the pre-checks prevent the upgrade process from continuing.

Workaround: Replace the STS certificate with a valid certificate that contains a SAN field then proceed with the vCenter Server 7.0 Upgrade/Migration.

Corrupted VFAT partitions from a vSphere 6.7 environment might cause upgrades to ESXi 7.x to fail

Due to corrupted VFAT partitions from a vSphere 6.7 environment, repartitioning the boot disks of an ESXi host might fail during an upgrade to ESXi 7.x. As a result, you might see the following errors:

When upgrading to ESXi 7.0 Update 3l, the operation fails with a purple diagnostic screen and/or an error such as:

- `An error occurred while backing up VFAT partition files before re-partitioning: Failed to calculate size for temporary Ramdisk: <error>.`
- `An error occurred while backing up VFAT partition files before re-partitioning: Failed to copy files to Ramdisk: <error>.`
  If you use an ISO installer, you see the errors, but no purple diagnostic screen.

When upgrading to an ESXi 7.x version earlier than 7.0 Update 3l, you might see:

- Logs such as `ramdisk (root) is full` in the `vmkwarning.log` file.
- Unexpected rollback to ESXi 6.5 or 6.7 on reboot.
- The `/bootbank`,`/altbootbank`, and ESX-OSData partitions are not present.

Workaround: You must first remediate the corrupted partitions before completing the upgrade to ESXi 7.x. For more details, see VMware knowledge base article 91136.

Problems upgrading to vSphere 7.0 with pre-existing CIM providers

After upgrade, previously installed 32-bit CIM providers stop working because ESXi requires 64-bit CIM providers. Customers may lose management API functions related to CIMPDK, NDDK (native DDK), HEXDK, VAIODK (IO filters), and see errors related to **uwglibc** dependency.

The syslog reports module missing, "32 bit shared libraries not loaded."

Workaround: There is no workaround. The fix is to download new 64-bit CIM providers from your vendor.

Installation of 7.0 Update 1 drivers on ESXi 7.0 hosts might fail

You cannot install drivers applicable to ESXi 7.0 Update 1 on hosts that run ESXi 7.0 or 7.0b.

The operation fails with an error, such as:

```
VMW_bootbank_qedrntv_3.40.4.0-12vmw.701.0.0.xxxxxxx requires vmkapi_2_7_0_0, but the
requirement cannot be satisfied within the ImageProfile. Please refer to the log file for
more details.
```

Workaround: Update the ESXi host to 7.0 Update 1. Retry the driver installation.

UEFI booting of ESXi hosts might stop with an error during an update to ESXi 7.0 Update 2 from an earlier version of ESXi 7.0

If you attempt to update your environment to 7.0 Update 2 from an earlier version of ESXi 7.0by using vSphere Lifecycle Manager patch baselines, UEFI booting of ESXi hosts might stop with an error such as:

```
Loading /boot.cfgFailed to load crypto64.efiFatal error: 15 (Not found)
```

Workaround: For more information, see VMware knowledge base articles 83063 and 83107 .

If legacy VIBs are in use on an ESXi host, vSphere Lifecycle Manager cannot extract a desired software specification to seed to a new cluster

With vCenter Server 7.0 Update 2, you can create a new cluster by importing the desired software specification from a single reference host. However, if legacy VIBs are in use on an ESXi host, vSphere Lifecycle Manager cannot extract in the vCenter Server instance where you create the cluster a reference software specification from such a host. In the `/var/log/lifecycle.log` , you see messages such as:

```
020-11-11T06:54:03Z lifecycle: 1000082644: HostSeeding:499
ERROR Extract depot failed: Checksum doesn't match. Calculated
5b404e28e83b1387841bb417da93c8c796ef2497c8af0f79583fd54e789d8826, expected:
0947542e30b794c721e21fb595f1851b247711d0619c55489a6a8cae6675e796 2020-11-11T06:54:04Z
lifecycle: 1000082644: imagemanagerctl:366 ERROR Extract depot failed.
2020-11-11T06:54:04Z lifecycle: 1000082644: imagemanagerctl:145 ERROR [VibChecksumError]
```

Workaround: Follow the steps described in VMware knowledge base article 83042.

You see a short burst of log messages in the syslog.log after every ESXi boot

After updating to ESXi 7.0 Update 2, you might see a short burst of log messages after every ESXi boot.

Such logs do not indicate any issue with ESXi and you can ignore these messages. For example:

```
2021-01-19T22:44:22Z watchdog-vaai-nasd: '/usr/lib/vmware/nfs/bin/vaai-nasd -f'

Workaround: None

You see warning messages for missing VIBs in vSphere Quick Boot compatibility check reports

After you upgrade to ESXi 7.0 Update 2, if you check vSphere Quick Boot compatibility of your environment by using the `/usr/lib/vmware/loadesx/bin/loadESXCheckCompat.py` command, you might see some warning messages for missing VIBs in the shell. For example:

```
Cannot find VIB(s) ... in the given VIB collection.Ignoring missing reserved VIB(s) ...,
they are removed from reserved VIB IDs.
```

Such warnings do not indicate a compatibility issue.

Workaround: The missing VIB messages can be safely ignored and do not affect the reporting of vSphere Quick Boot compatibility. The final output line of the `loadESXCheckCompat` command unambiguously indicates if the host is compatible.

Auto bootstrapping a cluster that you manage with a vSphere Lifecycle Manager image fails with an error

If you attempt auto bootstrapping a cluster that you manage with a vSphere Lifecycle Manager image to perform a stateful install and overwrite the VMFS partitions, the operation fails with an error. In the support bundle, you see messages such as:

```
2021-02-11T19:37:43Z Host Profiles[265671 opID=MainThread]: ERROR:
EngineModule::ApplyHostConfig. Exception: [Errno 30] Read-only file system
```

Workaround: Follow vendor guidance to clean the VMFS partition in the target host and retry the operation. Alternatively, use an empty disk. For more information on the disk-partitioning utility on ESXi, see VMware knowledge base article 1036609.

Upgrades to ESXi 7.x from 6.5.x and 6.7.0 by using ESXCLI might fail due to a space limitation

Upgrades to ESXi 7.x from 6.5.x and 6.7.0 by using the `esxcli software profile update` or `esxcli software profile install` ESXCLI commands might fail, because the ESXi bootbank might be less than the size of the image profile. In the ESXi Shell or the PowerCLI shell, you see an error such as:

```
[InstallationError]
 The pending transaction requires 244 MB free space, however the maximum supported size is 239 MB.
 Please refer to the log file for more details.
```

The issue also occurs when you attempt an ESXi host upgrade by using the ESXCLI commands `esxcli software vib update` or `esxcli software vib install`.

Workaround: You can perform the upgrade in two steps, by using the `esxcli software profile update` command to update ESXi hosts to ESXi 6.7 Update 1 or later, and then update to 7.0 Update 1c. Alternatively, you can run an upgrade by using an ISO image and the vSphere Lifecycle Manager.

You cannot migrate linked clones across vCenter Servers

If you migrate a linked clone across vCenter Servers, operations such as power on and delete might fail for the source virtual machine with an `Invalid virtual machine state` error.

Workaround: Keep linked clones on the same vCenter Server as the source VM. Alternatively, promote the linked clone to full clone before migration.

Migration across vCenter Servers of virtual machines with many virtual disks and snapshot levels to a datastore on NVMe over TCP storage might fail

Migration across vCenter Servers of virtual machines with more than 180 virtual disks and 32 snapshot levels to a datastore on NVMe over TCP storage might fail. The ESXi host preemptively fails with an error such as `The migration has exceeded the maximum switchover time of 100 second(s).`

Workaround: None

A virtual machine with enabled Virtual Performance Monitoring Counters (VPMC) might fail to migrate between ESXi hosts

If you try to migrate a virtual machine with enabled VPMC by using vSphere vMotion, the operation might fail if the target host is using some of the counters to compute memory or performance statistics. The operation fails with an error such as `A performance counter used by the guest is not available on the host CPU.`

Workaround: Power off the virtual machine and use cold migration. For more information, see VMware knowledge base article 81191.

If a live VIB install, upgrade, or remove operation immediately precedes an interactive or scripted upgrade to ESXi 7.0 Update 3 by using the installer ISO, the upgrade fails

When a VIB install, upgrade, or remove operation immediately precedes an interactive or scripted upgrade to ESXi 7.0 Update 3 by using the installer ISO, the ConfigStore might not keep some configurations of the upgrade. As a result, ESXi hosts become inaccessible after the upgrade operation, although the upgrade seems successful. To prevent this issue, the ESXi 7.0 Update 3 installer adds a temporary check to block such scenarios. In the ESXi installer console, you see the following error message: `Live VIB installation, upgrade or removal may cause subsequent ESXi upgrade to fail when using the ISO installer.`

Workaround: Use an alternative upgrade method to avoid the issue, such as using ESXCLI or the vSphere Lifecycle Manager.

Smart Card and RSA SecurID authentication might stop working after upgrading to vCenter Server 7.0

If you have configured vCenter Server for either Smart Card or RSA SecurID authentication, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057 before starting the vSphere 7.0 upgrade process. If you do not perform the workaround as described in the KB, you might see the following error messages and Smart Card or RSA SecurID authentication does not work.

"Smart card authentication may stop working. Smart card settings may not be preserved, and smart card authentication may stop working."

or

"RSA SecurID authentication may stop working. RSA SecurID settings may not be preserved, and RSA SecurID authentication may stop working."

Workaround: Before upgrading to vSphere 7.0, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057.

The vlanid property in custom installation scripts might not work

If you use a custom installation script that sets the `vlanid` property to specify a desired VLAN, the property might not take effect on newly installed ESXi hosts. The issue occurs only when a physical NIC is already connected to DHCP when the installation starts. The `vlanid` property works properly when you use a newly connected NIC.

Workaround: Manually set the VLAN from the Direct Console User Interface after you boot the ESXi host. Alternatively, disable the physical NIC and then boot the host.

HPE servers with Trusted Platform Module (TPM) boot, but remote attestation fails

Some HPE servers do not have enough event log space to properly finish TPM remote attestation. As a result, the VMkernel boots, but remote attestation fails due to the truncated log.

Workaround: None.

Upgrading a vCenter Server with an external Platform Services Controller from 6.7u3 to 7.0 fails with VMAFD error

When you upgrade a vCenter Server deployment using an external Platform Services Controller, you converge the Platform Services Controller into a vCenter Server appliance. If the upgrade fails with the error `install.vmafd.vmdir_vdcpromo_error_21` , the VMAFD firstboot process has failed. The VMAFD firstboot process copies the VMware Directory Service Database (data.mdb) from the source Platform Services Controller and replication partner vCenter Server appliance.

Workaround: Disable TCP Segmentation Offload (TSO) and Generic Segmentation Offload (GSO) on the Ethernet adapter of the source Platform Services Controller or replication partner vCenter Server appliance before upgrading a vCenter Server with an external Platform Services Controller. See Knowledge Base article: https://kb.vmware.com/s/article/74678

Smart card and RSA SecurID settings may not be preserved during vCenter Server upgrade

Authentication using RSA SecurID will not work after upgrading to vCenter Server 7.0. An error message will alert you to this issue when attempting to login using your RSA SecurID login.

Workaround: Reconfigure the smart card or RSA SecureID.

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with network error message

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with the error message `IP already exists in the network` . This prevents the migration process from configuring the network parameters on the new vCenter Server appliance. For more information, examine the log file: `/var/log/vmware/upgrade/UpgradeRunner.log`

Workaround:

1. Verify that all Windows Updates have been completed on the source vCenter Server for Windows instance, or disable automatic Windows Updates until after the migration finishes.
2. Retry the migration of vCenter Server for Windows to vCenter Server appliance 7.0.

When you configure the number of virtual functions for an SR-IOV device by using the max_vfs module parameter, the changes might not take effect

In vSphere 7.0, you can configure the number of virtual functions for an SR-IOV device by using the Virtual Infrastructure Management (VIM) API, for example, through the vSphere Client. The task does not require reboot of the ESXi host. After you use the VIM API configuration, if you try to configure the number of SR-IOV virtual functions by using the `max_vfs` module parameter, the changes might not take effect because they are overridden by the VIM API configuration.

Workaround: None. To configure the number of virtual functions for an SR-IOV device, use the same method every time. Use the VIM API or use the `max_vfs` module parameter and reboot the ESXi host.

Upgraded vCenter Server appliance instance does not retain all the secondary networks (NICs) from the source instance

During a major upgrade, if the source instance of the vCenter Server appliance is configured with multiple secondary networks other than the VCHA NIC, the target vCenter Server instance will not retain secondary networks other than the VCHA NIC. If the source instance is configured with multiple NICs that are part of VDS port groups, the NIC configuration

will not be preserved during the upgrade. Configurations for vCenter Server appliance instances that are part of the standard port group will be preserved.

Workaround: None. Manually configure the secondary network in the target vCenter Server appliance instance.

After upgrading or migrating a vCenter Server with an external Platform Services Controller, users authenticating using Active Directory lose access to the newly upgraded vCenter Server instance

After upgrading or migrating a vCenter Server with an external Platform Services Controller, if the newly upgraded vCenter Server is not joined to an Active Directory domain, users authenticating using Active Directory will lose access to the vCenter Server instance.

Workaround: Verify that the new vCenter Server instance has been joined to an Active Directory domain. See Knowledge Base article: https://kb.vmware.com/s/article/2118543

Migrating a vCenter Server for Windows with an external Platform Services Controller using an Oracle database fails

If there are non-ASCII strings in the Oracle events and tasks table the migration can fail when exporting events and tasks data. The following error message is provided: UnicodeDecodeError

Workaround: None.

After an ESXi host upgrade, a Host Profile compliance check shows non-compliant status while host remediation tasks fail

The non-compliant status indicates an inconsistency between the profile and the host.

This inconsistency might occur because ESXi 7.0 does not allow duplicate claim rules, but the profile you use contains duplicate rules. For example, if you attempt to use the Host Profile that you extracted from the host before upgrading ESXi 6.5 or ESXi 6.7 to version 7.0 and the Host Profile contains any duplicate claim rules of system default rules, you might experience the problems.

Workaround:

1. Remove any duplicate claim rules of the system default rules from the Host Profile document.
2. Check the compliance status.
3. Remediate the host.
4. If the previous steps do not help, reboot the host.

Error message displays in the vCenter Server Management Interface

After installing or upgrading to vCenter Server 7.0, when you navigate to the Update panel within the vCenter Server Management Interface, the error message "Check the URL and try again" displays. The error message does not prevent you from using the functions within the Update panel, and you can view, stage, and install any available updates.

Workaround: None.

Security Features Issues

Turn off the Service Location Protocol service in ESXi, slpd, to prevent potential security vulnerabilities

Some services in ESXi that run on top of the host operating system, including slpd, the CIM object broker, sfcbd, and the related openwsmand service, have proven security vulnerabilities. VMware has addressed all known vulnerabilities in VMSA-2019-0022 and VMSA-2020-0023, and the fixes are part of the vSphere 7.0 Update 2 release. While sfcbd and openwsmand are disabled by default in ESXi, slpd is enabled by default and you must turn it off, if not necessary, to prevent exposure to a future vulnerability after an upgrade.

Workaround: To turn off the slpd service, run the following PowerCLI commands:

```
$ Get-VMHost | Get-VmHostService | Where-Object {$_.key -eq "slpd"} | Set-VMHostService -policy "off"$ Get-VMHost | Get-VmHostService | Where-Object {$_.key -eq "slpd"} | Stop-VMHostService -Confirm:$false
```

Alternatively, you can use the command `chkconfig slpd off && /etc/init.d/slpd stop`.

The openwsmand service is not on the ESXi services list and you can check the service state by using the following PowerCLI commands:

```
$esx=(Get-EsxCli -vmhost xx.xx.xx.xx -v2)$esx.system.process.list.invoke() | where CommandLine -like '*openwsman*' | select commandline
```

In the ESXi services list, the sfcbd service appears as sfcbd-watchdog.

For more information, see VMware knowledge base articles 76372 and 1025757.

Encrypted virtual machine fails to power on when HA-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled HA on the Trusted Cluster and one or more hosts in the cluster fails attestation, an encrypted virtual machine cannot power on.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Encrypted virtual machine fails to power on when DRS-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled DRS on the Trusted Cluster and one or more hosts in the cluster fails attestation, DRS might try to power on an encrypted virtual machine on an unattested host in the cluster. This operation puts the virtual machine in a locked state.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Migrating or cloning encrypted virtual machines across vCenter Server instances fails when attempting to do so using the vSphere Client

If you try to migrate or clone an encrypted virtual machine across vCenter Server instances using the vSphere Client, the operation fails with the following error message: "The operation is not allowed in the current state."

Workaround: You must use the vSphere APIs to migrate or clone encrypted virtual machines across vCenter Server instances.

Networking Issues

Reduced throughput in networking performance on Intel 82599/X540/X550 NICs

The new queue-pair feature added to ixgben driver to improve networking performance on Intel 82599EB/X540/X550 series NICs might reduce throughput under some workloads in vSphere 7.0 as compared to vSphere 6.7.

Workaround: To achieve the same networking performance as vSphere 6.7, you can disable the queue-pair with a module parameter. To disable the queue-pair, run the command:

```
# esxcli system module parameters set -p "QPair=0,0,0,0..." -m ixgben
```

After running the command, reboot.

One or more I/O devices do not generate interrupts when the AMD IOMMU is in use

If the I/O devices on your ESXi host provide more than a total of 512 distinct interrupt sources, some sources are erroneously assigned an interrupt-remapping table entry (IRTE) index in the AMD IOMMU that is greater than the maximum value. Interrupts from such a source are lost, so the corresponding I/O device behaves as if interrupts are disabled.

Workaround: Use the ESXCLI command `esxcli system settings kernel set -s iovDisableIR -v true` to disable the AMD IOMMU interrupt remapper. Reboot the ESXi host so that the command takes effect.

When you set auto-negotiation on a network adapter, the device might fail

In some environments, if you set link speed to auto-negotiation for network adapters by using the command `esxcli network nic set -a -n vmmicx` , the devices might fail and reboot does not recover connectivity. The issue is specific to a combination of some Intel X710/X722 network adapters, a SFP+ module and a physical switch, where auto-negotiate speed/duplex scenario is not supported.

Workaround: Make sure you use an Intel-branded SFP+ module. Alternatively, use a Direct Attach Copper (DAC) cable.

Solarflare x2542 and x2541 network adapters configured in 1x100G port mode achieve throughput of up to 70Gbps in a vSphere environment

vSphere 7.0 Update 2 supports Solarflare x2542 and x2541 network adapters configured in 1x100G port mode. However, you might see a hardware limitation in the devices that causes the actual throughput to be up to some 70Gbps in a vSphere environment.

Workaround: None

VLAN traffic might fail after a NIC reset

A NIC with PCI device ID 8086:1537 might stop to send and receive VLAN tagged packets after a reset, for example, with a command `vsish -e set /net/pNics/vmnic0/reset 1` .

Workaround: Avoid resetting the NIC. If you already face the issue, use the following commands to restore the VLAN capability, for example at vmnic0:

```
# esxcli network nic software set --tagging=1 -n vmnic0# esxcli network nic software set
--tagging=0 -n vmnic0
```

Any change in the NetQueue balancer settings causes NetQueue to be disabled after an ESXi host reboot

Any change in the NetQueue balancer settings by using the command `esxcli/localcli network nic queue loadbalancer set -n <nicname> --<lb_setting>` causes NetQueue, which is enabled by default, to be disabled after an ESXi host reboot.

Workaround: After a change in the NetQueue balancer settings and host reboot, use the command `configstorecli config current get -c esx -g network -k nics` to retrieve ConfigStore data to verify whether the `/esx/network/nics/net_queue/load_balancer/enable` is working as expected.

After you run the command, you see output similar to:

```
{"mac": "02:00:0e:6d:14:3e","name": "vmnic1","net_queue": { "load_balancer":
{ "dynamic_pool": true, "enable": true }},"virtual_mac": "00:50:56:5a:21:11"}
```

If the output is not as expected, for example `"load_balancer": "enable": false"` , run the following command:

```
esxcli/localcli network nic queue loadbalancer state set -n <nicname> -e true
```

Paravirtual RDMA (PVRDMA) network adapters do not support NSX networking policies

If you configure an NSX distributed virtual port for use in PVRDMA traffic, the RDMA protocol traffic over the PVRDMA network adapters does not comply with the NSX network policies.

Workaround: Do not configure NSX distributed virtual ports for use in PVRDMA traffic.

Rollback from converged vSphere Distributed Switch (VDS) to NSX-T VDS is not supported in vSphere 7.0 Update 3

Rollback from converged VDS that supports both vSphere 7 traffic and NSX-T 3 traffic on the same VDS to one N-VDS for NSX-T traffic is not supported in vSphere 7.0 Update 3.

Workaround: None

If you do not set the nmlx5 network driver module parameter, network connectivity or ESXi hosts might fail

If you do not set the `supported_num_ports` module parameter for the `nmlx5_core` driver on an ESXi host with multiple network adapters of versions Mellanox ConnectX-4, Mellanox ConnectX-5 and Mellanox ConnectX-6, the driver might not allocate sufficient memory for operating all the NIC ports for the host. As a result, you might experience network loss or ESXi host failure with purple diagnostic screen, or both.

Workaround: Set the `supported_num_ports` module parameter value in the `nmlx5_core` network driver equal to the total number of Mellanox ConnectX-4, Mellanox ConnectX-5 and Mellanox ConnectX-6 network adapter ports on the ESXi host.

High throughput virtual machines may experience degradation in network performance when Network I/O Control (NetIOC) is enabled

Virtual machines requiring high network throughput can experience throughput degradation when upgrading from vSphere 6.7 to vSphere 7.0 with NetIOC enabled.

Workaround: Adjust the `ethernetx.ctxPerDev` setting to enable multiple worlds.

IPv6 traffic fails to pass through VMkernel ports using IPsec

When you migrate VMkernel ports from one port group to another, IPv6 traffic does not pass through VMkernel ports using IPsec.

Workaround: Remove the IPsec security association (SA) from the affected server, and then reapply the SA. To learn how to set and remove an IPsec SA, see the *vSphere Security* documentation.

Higher ESX network performance with a portion of CPU usage increase

ESX network performance may increase with a portion of CPU usage.

Workaround: Remove and add the network interface with only 1 rx dispatch queue. For example:

```
esxcli network ip interface remove --interface-name=vmk1
esxcli network ip interface add --interface-name=vmk1 --num-rxqueue=1
```

VM might lose Ethernet traffic after hot-add, hot-remove or storage vMotion

A VM might stop receiving Ethernet traffic after a hot-add, hot-remove or storage vMotion. This issue affects VMs where the uplink of the VNIC has SR-IOV enabled. PVRDMA virtual NIC exhibits this issue when the uplink of the virtual network is a Mellanox RDMA capable NIC and RDMA namespaces are configured.

Workaround: You can hot-remove and hot-add the affected Ethernet NICs of the VM to restore traffic. On Linux guest operating systems, restarting the network might also resolve the issue. If these workarounds have no effect, you can reboot the VM to restore network connectivity.

Change of IP address for a VCSA deployed with static IP address requires that you create the DNS records in advance

With the introduction of the DDNS, the DNS record update only works for VCSA deployed with DHCP configured networking. While changing the IP address of the vCenter server via VAMI, the following error is displayed:

The specified IP address does not resolve to the specified hostname.

Workaround: There are two possible workarounds.

1. Create an additional DNS entry with the same FQDN and desired IP address. Log in to the VAMI and follow the steps to change the IP address.
2. Log in to the VCSA using ssh. Execute the following script:
   `./opt/vmware/share/vami/vami_config_net`
   Use option 6 to change the IP adddress of eth0. Once changed, execute the following script:
   `./opt/likewise/bin/lw-update-dns`
   Restart all the services on the VCSA to update the IP information on the DNS server.

It may take several seconds for the NSX Distributed Virtual Port Group (NSX DVPG) to be removed after deleting the corresponding logical switch in NSX Manager.

As the number of logical switches increases, it may take more time for the NSX DVPG in vCenter Server to be removed after deleting the corresponding logical switch in NSX Manager. In an environment with 12000 logical switches, it takes approximately 10 seconds for an NSX DVPG to be deleted from vCenter Server.

Workaround: None.

Hostd runs out of memory and fails if a large number of NSX Distributed Virtual port groups are created.

In vSphere 7.0, NSX Distributed Virtual port groups consume significantly larger amounts of memory than opaque networks. For this reason, NSX Distributed Virtual port groups can not support the same scale as an opaque network given the same amount of memory.

Workaround:To support the use of NSX Distributed Virtual port groups, increase the amount of memory in your ESXi hosts. If you verify that your system has adequate memory to support your VMs, you can directly increase the memory of `hostd` using the following command.

```
localcli --plugin-dir /usr/lib/vmware/esxcli/int/ sched group setmemconfig --group-path
host/vim/vmvisor/hostd --units mb --min 2048 --max 2048
```

Note that this will cause `hostd` to use memory normally reserved for your environment's VMs. This may have the affect of reducing the number of VMs your ESXi host can support.

DRS may incorrectly launch vMotion if the network reservation is configured on a VM

If the network reservation is configured on a VM, it is expected that DRS only migrates the VM to a host that meets the specified requirements. In a cluster with NSX transport nodes, if some of the transport nodes join the transport zone by NSX-T Virtual Distributed Switch (N-VDS), and others by vSphere Distributed Switch (VDS) 7.0, DRS may incorrectly launch vMotion. You might encounter this issue when:

- The VM connects to an NSX logical switch configured with a network reservation.
- Some transport nodes join transport zone using N-VDS, and others by VDS 7.0, or, transport nodes join the transport zone through different VDS 7.0 instances.

Workaround: Make all transport nodes join the transport zone by N-VDS or the same VDS 7.0 instance.

When adding a VMkernel NIC (vmknic) to an NSX portgroup, vCenter Server reports the error "Connecting VMKernel adapter to a NSX Portgroup on a Stateless host is not a supported operation. Please use Distributed Port Group instead."

- For stateless ESXi on Distributed Virtual Switch (VDS), the vmknic on a NSX port group is blocked. You must instead use a Distributed Port Group.
- For stateful ESXi on VDS, vmknic on NSX port group is supported, but vSAN may have an issue if it is using vmknic on a NSX port group.

Workaround: Use a Distributed Port Group on the same VDS.

Enabling SRIOV from vCenter for QLogic 4x10GE QL41164HFCU CNA might fail

If you navigate to the **Edit Settings** dialog for physical network adapters and attempt to enable SR-IOV, the operation might fail when using QLogic 4x10GE QL41164HFCU CNA. Attempting to enable SR-IOV might lead to a network outage of the ESXi host.

Workaround: Use the following command on the ESXi host to enable SRIOV:

```
esxcfg-module
```

vCenter Server fails if the hosts in a cluster using Distributed Resource Scheduler (DRS) join NSX-T networking by a different Virtual Distributed Switch (VDS) or combination of NSX-T Virtual Distributed Switch (NVDS) and VDS

In vSphere 7.0, when using NSX-T networking on vSphere VDS with a DRS cluster, if the hosts do not join the NSX transport zone by the same VDS or NVDS, it can cause vCenter Server to fail.

Workaround: Have hosts in a DRS cluster join the NSX transport zone using the same VDS or NVDS.

Storage Issues

VMFS datastores are not mounted automatically after disk hot remove and hot insert on HPE Gen10 servers with SmartPQI controllers

When SATA disks on HPE Gen10 servers with SmartPQI controllers without expanders are hot removed and hot inserted back to a different disk bay of the same machine, or when multiple disks are hot removed and hot inserted back in a different order, sometimes a new local name is assigned to the disk. The VMFS datastore on that disk appears as a snapshot and will not be mounted back automatically because the device name has changed.

Workaround: None. SmartPQI controller does not support unordered hot remove and hot insert operations.

VOMA check on NVMe based VMFS datastores fails with error

VOMA check is not supported for NVMe based VMFS datastores and will fail with the error:

```
ERROR: Failed to reserve device. Function not implemented
```

Example:

```
# voma -m vmfs -f check -d /vmfs/devices/disks/: <partition#>
Running VMFS Checker version 2.1 in check mode
Initializing LVM metadata, Basic Checks will be done

Checking for filesystem activity
Performing filesystem liveness check..|Scanning for VMFS-6 host activity (4096 bytes/HB, 1024 HBs).
ERROR: Failed to reserve device. Function not implemented
Aborting VMFS volume check
VOMA failed to check device : General Error
```

Workaround: None. If you need to analyse VMFS metadata, collect it using the `-l` option, and pass to VMware customer support. The command for collecting the dump is:

```
voma -l -f dump -d /vmfs/devices/disks/:<partition#>
```

Using the VM reconfigure API to attach an encrypted First Class Disk to an encrypted virtual machine might fail with error

If an FCD and a VM are encrypted with different crypto keys, your attempts to attach the encrypted FCD to the encrypted VM using the `VM reconfigure API` might fail with the error message:

```
Cannot decrypt disk because key or password is incorrect.
```

Workaround: Use the `attachDisk API` rather than the `VM reconfigure API` to attach an encrypted FCD to an encrypted VM.

ESXi host might get in non responding state if a non-head extent of its spanned VMFS datastore enters the Permanent Device Loss (PDL) state

This problem does not occur when a non-head extent of the spanned VMFS datastore fails along with the head extent. In this case, the entire datastore becomes inaccessible and no longer allows I/Os.

In contrast, when only a non-head extent fails, but the head extent remains accessible, the datastore heartbeat appears to be normal. And the I/Os between the host and the datastore continue. However, any I/Os that depend on the failed non-head extent start failing as well. Other I/O transactions might accumulate while waiting for the failing I/Os to resolve, and cause the host to enter the non responding state.

Workaround: Fix the PDL condition of the non-head extent to resolve this issue.

Virtual NVMe Controller is the default disk controller for Windows 10 guest operating systems

The Virtual NVMe Controller is the default disk controller for the following guest operating systems when using Hardware Version 15 or later:

Windows 10

Windows Server 2016

Windows Server 2019

Some features might not be available when using a Virtual NVMe Controller. For more information, see https://kb.vmware.com/s/article/2147714

Note: Some clients use the previous default of LSI Logic SAS. This includes ESXi host client and PowerCLI.

Workaround: If you need features not available on Virtual NVMe, switch to VMware Paravirtual SCSI (PVSCSI) or LSI Logic SAS. For information on using VMware Paravirtual SCSI (PVSCSI), see https://kb.vmware.com/s/article/1010398

After an ESXi host upgrade to vSphere 7.0, presence of duplicate core claim rules might cause unexpected behavior

Claim rules determine which multipathing plugin, such as NMP, HPP, and so on, owns paths to a particular storage device. ESXi 7.0 does not support duplicate claim rules. However, the ESXi 7.0 host does not alert you if you add duplicate rules to the existing claim rules inherited through an upgrade from a legacy release. As a result of using duplicate rules, storage devices might be claimed by unintended plugins, which can cause unexpected outcome.

Workaround: Do not use duplicate core claim rules. Before adding a new claim rule, delete any existing matching claim rule.

A CNS query with the compliance status filter set might take unusually long time to complete

The CNS QueryVolume API enables you to obtain information about the CNS volumes, such as volume health and compliance status. When you check the compliance status of individual volumes, the results are obtained quickly. However, when you invoke the CNS QueryVolume API to check the compliance status of multiple volumes, several tens or hundreds, the query might perform slowly.

Workaround: Avoid using bulk queries. When you need to get compliance status, query one volume at a time or limit the number of volumes in the query API to 20 or fewer. While using the query, avoid running other CNS operations to get the best performance.

A VMFS datastore backed by an NVMe over Fabrics namespace or device might become permanently inaccessible after recovering from an APD or PDL failure

If a VMFS datastore on an ESXi host is backed by an NVMe over Fabrics namespace or device, in case of an all paths down (APD) or permanent device loss (PDL) failure, the datastore might be inaccessible even after recovery. You cannot access the datastore from either the ESXi host or the vCenter Server system.

Workaround: To recover from this state, perform a rescan on a host or cluster level. For more information, see Perform Storage Rescan.

Deleted CNS volumes might temporarily appear as existing in the CNS UI

After you delete an FCD disk that backs a CNS volume, the volume might still show up as existing in the CNS UI. However, your attempts to delete the volume fail. You might see an error message similar to the following:

```
The object or item referred to could not be found.
```

Workaround: The next full synchronization will resolve the inconsistency and correctly update the CNS UI.

Attempts to attach multiple CNS volumes to the same pod might occasionally fail with an error

When you attach multiple volumes to the same pod simultaneously, the attach operation might occasionally choose the same controller slot. As a result, only one of the operations succeeds, while other volume mounts fail.

Workaround: After Kubernetes retries the failed operation, the operation succeeds if a controller slot is available on the node VM.

Under certain circumstances, while a CNS operation fails, the task status appears as successful in the vSphere Client

This might occur when, for example, you use an incompliant storage policy to create a CNS volume. The operation fails, while the vSphere Client shows the task status as successful.

Workaround: The successful task status in the vSphere Client does not guarantee that the CNS operation succeeded. To make sure the operation succeeded, verify its results.

Unsuccessful delete operation for a CNS persistent volume might leave the volume undeleted on the vSphere datastore

This issue might occur when the CNS Delete API attempts to delete a persistent volume that is still attached to a pod. For example, when you delete the Kubernetes namespace where the pod runs. As a result, the volume gets cleared from CNS and the CNS query operation does not return the volume. However, the volume continues to reside on the datastore and cannot be deleted through the repeated CNS Delete API operations.

Workaround: None.

vCenter Server and vSphere Client Issues

Vendor providers go offline after a PNID change

When you change the vCenter IP address (PNID change), the registered vendor providers go offline.

Workaround: Re-register the vendor providers.

Cross vCenter migration of a virtual machine fails with an error

When you use cross vCenter vMotion to move a VM's storage and host to a different vCenter server instance, you might receive the error `The operation is not allowed in the current state.`

This error appears in the UI wizard after the Host Selection step and before the Datastore Selection step, in cases where the VM has an assigned storage policy containing host-based rules such as encryption or any other IO filter rule.

Workaround: Assign the VM and its disks to a storage policy without host-based rules. You might need to decrypt the VM if the source VM is encrypted. Then retry the cross vCenter vMotion action.

Storage Sensors information in Hardware Health tab shows incorrect values on vCenter UI, host UI, and MOB

When you navigate to **Host > Monitor > Hardware Health > Storage Sensors** on vCenter UI, the storage information displays either incorrect or unknown values. The same issue is observed on the host UI and the MOB path `"runtime.hardwareStatusInfo.storageStatusInfo"` as well.

Workaround: None.

vSphere UI host advanced settings shows the current product locker location as empty with an empty default

vSphere UI host advanced settings shows the current product locker location as empty with an empty default. This is inconsistent as the actual product location `symlink` is created and valid. This causes confusion to the user. The default cannot be corrected from UI.

Workaround: User can use the esxcli command on the host to correct the current product locker location default as below.

1. Remove the existing Product Locker Location setting with: `"esxcli system settings advanced remove -o ProductLockerLocation"`

2. Re-add the Product Locker Location setting with the appropriate default:

2.a. If the ESXi is a full installation, the default value is `"/locker/packages/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/locker/packages/vmtoolsRepo"`

2.b. If the ESXi is a PXEboot configuration such as autodeploy, the default value is: `"/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/vmtoolsRepo"`

Run the following command to automatically figure out the location: `export PRODUCT_LOCKER_DEFAULT=`readlink /productLocker``

Add the setting: `esxcli system settings advanced add -d "Path to VMware Tools repository" -o ProductLockerLocation -t string -s $PRODUCT_LOCKER_DEFAULT`

You can combine all the above steps in step 2 by issuing the single command:

```
esxcli system settings advanced add -d "Path to VMware Tools repository" -o
ProductLockerLocation -t string -s `readlink /productLocker`
```

Linked Software-Defined Data Center (SDDC) vCenter Server instances appear in the on-premises vSphere Client if a vCenter Cloud Gateway is linked to the SDDC.

When a vCenter Cloud Gateway is deployed in the same environment as an on-premises vCenter Server, and linked to an SDDC, the SDDC vCenter Server will appear in the on-premises vSphere Client. This is unexpected behavior and the linked SDDC vCenter Server should be ignored. All operations involving the linked SDDC vCenter Server should be performed on the vSphere Client running within the vCenter Cloud Gateway.

Workaround: None.

Virtual Machine Management Issues

UEFI HTTP booting of virtual machines on ESXi hosts of version earlier than 7.0 Update 2 fails

UEFI HTTP booting of virtual machines is supported only on hosts of version ESXi 7.0 Update 2 and later and VMs with HW version 19 or later.

Workaround: Use UEFI HTTP booting only in virtual machines with HW version 19 or later. Using HW version 19 ensures the virtual machines are placed only on hosts with ESXi version 7.0 Update 2 or later.

Virtual machine snapshot operations fail in vSphere Virtual Volumes datastores on Purity version 5.3.10

Virtual machine snapshot operations fail in vSphere Virtual Volumes datastores on Purity version 5.3.10 with an error such as `An error occurred while saving the snapshot: The VVol target encountered a vendor specific error`. The issue is specific for Purity version 5.3.10.

Workaround: Upgrade to Purity version 6.1.7 or follow vendor recommendations.

The postcustomization section of the customization script runs before the guest customization

When you run the guest customization script for a Linux guest operating system, the `precustomization` section of the customization script that is defined in the customization specification runs before the guest customization and the `postcustomization` section runs after that. If you enable Cloud-Init in the guest operating system of a virtual machine, the `postcustomization` section runs before the customization due to a known issue in Cloud-Init.

Workaround: Disable Cloud-Init and use the standard guest customization.

Group migration operations in vSphere vMotion, Storage vMotion, and vMotion without shared storage fail with error

When you perform group migration operations on VMs with multiple disks and multi-level snapshots, the operations might fail with the error `com.vmware.vc.GenericVmConfigFault Failed waiting for data. Error 195887167. Connection closed by remote host, possibly due to timeout.`

Workaround: Retry the migration operation on the failed VMs one at a time.

Deploying an OVF or OVA template from a URL fails with a 403 Forbidden error

The URLs that contain an HTTP query parameter are not supported. For example, `http://webaddress.com?file=abc.ovf` or the Amazon pre-signed S3 URLs.

Workaround: Download the files and deploy them from your local file system.

The third level of nested objects in a virtual machine folder is not visible

Perform the following steps:

1. Navigate to a data center and create a virtual machine folder.
2. In the virtual machine folder, create a nested virtual machine folder.
3. In the second folder, create another nested virtual machine, virtual machine folder, vApp, or VM Template.

As a result, from the VMs and Templates inventory tree you cannot see the objects in the third nested folder.

Workaround: To see the objects in the third nested folder, navigate to the second nested folder and select the VMs tab.

vSphere HA and Fault Tolerance Issues

VMs in a cluster might be orphaned after recovering from storage inaccessibility such as a cluster wide APD

Some VMs might be in orphaned state after cluster wide APD recovers, even if HA and VMCP are enabled on the cluster.

This issue might be encountered when the following conditions occur simultaneously:

- All hosts in the cluster experience APD and do not recover until VMCP timeout is reached.
- HA primary initiates failover due to APD on a host.
- Power on API during HA failover fails due to one of the following:
  - APD across the same host
  - Cascading APD across the entire cluster
  - Storage issues
  - Resource unavailability

- FDM unregistration and VCs steal VM logic might initiate during a window where FDM has not unregistered the failed VM and VC's host synchronization responds that multiple hosts are reporting the same VM. Both FDM and VC unregister the different registered copies of the same VM from different hosts, causing the VM to be orphaned.

Workaround: You must unregister and reregister the orphaned VMs manually within the cluster after the APD recovers.

If you do not manually reregister the orphaned VMs, HA attempts failover of the orphaned VMs, but it might take between 5 to 10 hours depending on when APD recovers.

The overall functionality of the cluster is not affected in these cases and HA will continue to protect the VMs. This is an anomaly in what gets displayed on VC for the duration of the problem.

vSphere Lifecycle Manager Issues

vSphere Lifecycle Manager and vSAN File Services cannot be simultaneously enabled on a vSAN cluster in vSphere 7.0 release

If vSphere Lifecycle Manager is enabled on a cluster, vSAN File Services cannot be enabled on the same cluster and vice versa. In order to enable vSphere Lifecycle Manager on a cluster, which has VSAN File Services enabled already, first disable vSAN File Services and retry the operation. Please note that if you transition to a cluster that is managed by a single image, vSphere Lifecycle Manager cannot be disabled on that cluster.

Workaround: None.

When a hardware support manager is unavailable, vSphere High Availability (HA) functionality is impacted

If hardware support manager is unavailable for a cluster that you manage with a single image, where a firmware and drivers addon is selected and vSphere HA is enabled, the vSphere HA functionality is impacted. You may experience the following errors.

- Configuring vSphere HA on a cluster fails.
- Cannot complete the configuration of the vSphere HA agent on a host: `Applying HA VIBs on the cluster encountered a failure.`
- Remediating vSphere HA fails: `A general system error occurred: Failed to get Effective Component map.`
- Disabling vSphere HA fails: Delete Solution task failed. `A general system error occurred: Cannot find hardware support package from depot or hardware support manager.`

Workaround:

- If the hardware support manager is temporarily unavailable, perform the following steps.

1. Reconnect the hardware support manager to vCenter Server.
2. Select a cluster from the Hosts and Cluster menu.
3. Select the Configure tab.
4. Under Services, click vSphere Availability.
5. Re-enable vSphere HA.

- If the hardware support manager is permanently unavailable, perform the following steps.

1. Remove the hardware support manager and the hardware support package from the image specification
2. Re-enable vSphere HA.
3. Select a cluster from the Hosts and Cluster menu.
4. Select the Updates tab.
5. Click Edit .
6. Remove the firmware and drivers addon and click Save.

7. Select the Configure tab.
8. Under Services, click vSphere Availability.
9. Re-enable vSphere HA.

I/OFilter is not removed from a cluster after a remediation process in vSphere Lifecycle Manager

Removing I/OFilter from a cluster by remediating the cluster in vSphere Lifecycle Manager, fails with the following error message: `iofilter XXX already exists`. The iofilter remains listed as installed.

Workaround:

1. Call IOFilter API `UninstallIoFilter_Task` from the vCenter Server managed object (IoFilterManager).
2. Remediate the cluster in vSphere Lifecycle Manager.
3. Call IOFilter API `ResolveInstallationErrorsOnCluster_Task` from the vCenter Server managed object (IoFilterManager) to update the database.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, adding hosts causes a vSphere HA error state

Adding one or multiple ESXi hosts during a remediation process of a vSphere HA enabled cluster, results in the following error message: `Applying HA VIBs on the cluster encountered a failure.`

Workaround: After the cluster remediation operation has finished, perform one of the following tasks.

- Right-click the failed ESXi host and select *Reconfigure for vSphere HA*.
- Disable and re-enable vSphere HA for the cluster.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, disabling and re-enabling vSphere HA causes a vSphere HA error state

Disabling and re-enabling vSphere HA during remediation process of a cluster, may fail the remediation process due to vSphere HA health checks reporting that hosts don't have vSphere HA VIBs installed. You may see the following error message: `Setting desired image spec for cluster failed.`

Workaround: After the cluster remediation operation has finished, disable and re-enable vSphere HA for the cluster.

Checking for recommended images in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the recommendation generation task could take more than an hour to finish or may appear to hang. The completion time for the recommendation task depends on the number of devices configured on each host and the number of image candidates from the depot that vSphere Lifecycle Manager needs to process before obtaining a valid image to recommend.

Workaround: None.

Checking for hardware compatibility in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the validation report generation task could take up to 30 minutes to finish or may appear to hang. The completion time depends on the number of devices configured on each host and the number of hosts configured in the cluster.

Workaround: None

Incomplete error messages in non-English languages are displayed, when remediating a cluster in vSphere Lifecycle Manager

You can encounter incomplete error messages for localized languages in the vCenter Server user interface. The messages are displayed, after a cluster remediation process in vSphere Lifecycle Manager fails. For example, your can observe the following error message.

The error message in English language: `Virtual machine 'VMC on DELL EMC -FileServer' that runs on cluster 'Cluster-1' reported an issue which prevents entering maintenance mode: Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

The error message in French language: `La VM « VMC on DELL EMC -FileServer », située sur le cluster « {Cluster-1} », a signalé un problème empêchant le passage en mode de maintenance : Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

Workaround: None.

Importing an image with no vendor addon, components, or firmware and drivers addon to a cluster which image contains such elements, does not remove the image elements of the existing image

Only the ESXi base image is replaced with the one from the imported image.

Workaround: After the import process finishes, edit the image, and if needed, remove the vendor addon, components, and firmware and drivers addon.

When you convert a cluster that uses baselines to a cluster that uses a single image, a warning is displayed that vSphere HA VIBs will be removed

Converting a vSphere HA enabled cluster that uses baselines to a cluster that uses a single image, may result a warning message displaying that `vmware-fdm` component will be removed.

Workaround: This message can be ignored. The conversion process installs the `vmware-fdm` component.

If vSphere Update Manager is configured to download patch updates from the Internet through a proxy server, after upgrade to vSphere 7.0 that converts Update Manager to vSphere Lifecycle Manager, downloading patches from VMware patch repository might fail

In earlier releases of vCenter Server you could configure independent proxy settings for vCenter Server and vSphere Update Manager. After an upgrade to vSphere 7.0, vSphere Update Manager service becomes part of the vSphere Lifecycle Manager service. For the vSphere Lifecycle Manager service, the proxy settings are configured from the vCenter Server appliance settings. If you had configured Update Manager to download patch updates from the Internet through a proxy server but the vCenter Server appliance had no proxy setting configuration, after a vCenter Server upgrade to version 7.0, the vSphere Lifecycle Manager fails to connect to the VMware depot and is unable to download patches or updates.

Workaround: Log in to the vCenter Server Appliance Management Interface, https://*vcenter-server-appliance-FQDN-or-IP-address*:5480, to configure proxy settings for the vCenter Server appliance and enable vSphere Lifecycle Manager to use proxy.

Miscellaneous Issues

When applying a host profile with version 6.5 to a ESXi host with version 7.0, the compliance check fails

Applying a host profile with version 6.5 to a ESXi host with version 7.0, results in Coredump file profile reported as not compliant with the host.

Workaround: There are two possible workarounds.

1. When you create a host profile with version 6.5, set an advanced configuration option VMkernel.Boot.autoCreateDumpFile to false on the ESXi host.
2. When you apply an existing host profile with version 6.5, add an advanced configuration option VMkernel.Boot.autoCreateDumpFile in the host profile, configure the option to a fixed policy, and set value to false.

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit minor throughput degradation when Dynamic Receive Side Scaling (DYN_RSS) or Generic RSS (GEN_RSS) feature is turned on

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit less than 5 percent throughput degradation when DYN_RSS and GEN_RSS feature is turned on, which is unlikely to impact normal workloads.

Workaround: You can disable DYN_RSS and GEN_RSS feature with the following commands:

```
# esxcli system module parameters set -m nmlx5_core -p "DYN_RSS=0 GEN_RSS=0"
# reboot
```

RDMA traffic between two VMs on the same host might fail in PVRDMA environment

In a vSphere 7.0 implementation of a PVRDMA environment, VMs pass traffic through the HCA for local communication if an HCA is present. However, loopback of RDMA traffic does not work on qedrntv driver. For instance, RDMA Queue Pairs running on VMs that are configured under same uplink port cannot communicate with each other.

In vSphere 6.7 and earlier, HCA was used for local RDMA traffic if SRQ was enabled. vSphere 7.0 uses HCA loopback with VMs using versions of PVRDMA that have SRQ enabled with a minimum of HW v14 using RoCE v2.

The current version of Marvell FastLinQ adapter firmware does not support loopback traffic between QPs of the same PF or port.

Workaround: Required support is being added in the out-of-box driver certified for vSphere 7.0. If you are using the inbox qedrntv driver, you must use a 3-host configuration and migrate VMs to the third host.

Unreliable Datagram traffic QP limitations in qedrntv driver

There are limitations with the Marvell FastLinQ qedrntv RoCE driver and Unreliable Datagram (UD) traffic. UD applications involving bulk traffic might fail with qedrntv driver. Additionally, UD QPs can only work with DMA Memory Regions (MR). Physical MRs or FRMR are not supported. Applications attempting to use physical MR or FRMR along with UD QP fail to pass traffic when used with qedrntv driver. Known examples of such test applications are `ibv_ud_pingpong` and `ib_send_bw`.

Standard RoCE and RoCEv2 use cases in a VMware ESXi environment such as iSER, NVMe-oF (RoCE) and PVRDMA are not impacted by this issue. Use cases for UD traffic are limited and this issue impacts a small set of applications requiring bulk UD traffic.

Marvell FastLinQ hardware does not support RDMA UD traffic offload. In order to meet the VMware PVRDMA requirement to support GSI QP, a restricted software only implementation of UD QP support was added to the qedrntv driver. The goal of the implementation is to provide support for control path GSI communication and is not a complete implementation of UD QP supporting bulk traffic and advanced features.

Since UD support is implemented in software, the implementation might not keep up with heavy traffic and packets might be dropped. This can result in failures with bulk UD traffic.

Workaround: Bulk UD QP traffic is not supported with qedrntv driver and there is no workaround at this time. VMware ESXi RDMA (RoCE) use cases like iSER, NVMe, RDMA and PVRDMA are unaffected by this issue.

Servers equipped with QLogic 578xx NIC might fail when frequently connecting or disconnecting iSCSI LUNs

If you trigger QLogic 578xx NIC iSCSI connection or disconnection frequently in a short time, the server might fail due to an issue with the qfle3 driver. This is caused by a known defect in the device's firmware.

Workaround: None.

ESXi might fail during driver unload or controller disconnect operation in Broadcom NVMe over FC environment

In Broadcom NVMe over FC environment, ESXi might fail during driver unload or controller disconnect operation and display an error message such as: `@BlueScreen: #PF Exception 14 in world 2098707:vmknvmeGener IP 0x4200225021cc addr 0x19`

Workaround: None.

ESXi does not display OEM firmware version number of i350/X550 NICs on some Dell servers

The inbox ixgben driver only recognizes firmware data version or signature for i350/X550 NICs. On some Dell servers the OEM firmware version number is programmed into the OEM package version region, and the inbox ixgben driver does not read this information. Only the 8-digit firmware signature is displayed.

Workaround: To display the OEM firmware version number, install async ixgben driver version 1.7.15 or later.

X710 or XL710 NICs might fail in ESXi

When you initiate certain destructive operations to X710 or XL710 NICs, such as resetting the NIC or manipulating VMKernel's internal device tree, the NIC hardware might read data from non-packet memory.

Workaround: Do not reset the NIC or manipulate vmkernel internal device state.

NVMe-oF does not guarantee persistent VMHBA name after system reboot

NVMe-oF is a new feature in vSphere 7.0. If your server has a USB storage installation that uses vmhba30+ and also has NVMe over RDMA configuration, the VMHBA name might change after a system reboot. This is because the VMHBA name assignment for NVMe over RDMA is different from PCIe devices. ESXi does not guarantee persistence.

Workaround: None.

Backup fails for vCenter database size of 300 GB or greater

If the vCenter database size is 300 GB or greater, the file-based backup will fail with a timeout. The following error message is displayed: `Timeout! Failed to complete in 72000 seconds`

Workaround: None.

A restore of vCenter Server 7.0 which is upgraded from vCenter Server 6.x with External Platform Services Controller to vCenter Server 7.0 might fail

When you restore a vCenter Server 7.0 which is upgraded from 6.x with External Platform Services Controller to vCenter Server 7.0, the restore might fail and display the following error: `Failed to retrieve appliance storage list`

Workaround: During the first stage of the restore process, increase the storage level of the vCenter Server 7.0. For example if the vCenter Server 6.7 External Platform Services Controller setup storage type is small, select storage type large for the restore process.

Enabled SSL protocols configuration parameter is not configured during a host profile remediation process

`Enabled SSL protocols` configuration parameter is not configured during a host profile remediation and only the system default protocol `tlsv1.2` is enabled. This behavior is observed for a host profile with version 7.0 and earlier in a vCenter Server 7.0 environment.

Workaround: To enable TLSV 1.0 or TLSV 1.1 SSL protocols for SFCB, log in to an ESXi host by using SSH, and run the following ESXCLI command: `esxcli system wbem -P <protocol_name>`

Unable to configure Lockdown Mode settings by using Host Profiles

Lockdown Mode cannot be configured by using a security host profile and cannot be applied to multiple ESXi hosts at once. You must manually configure each host.

Workaround: In vCenter Server 7.0, you can configure Lockdown Mode and manage Lockdown Mode exception user list by using a security host profile.

When a host profile is applied to a cluster, Enhanced vMotion Compatibility (EVC) settings are missing from the ESXi hosts

Some settings in the VMware config file `/etc/vmware/config` are not managed by Host Profiles and are blocked, when the config file is modified. As a result, when the host profile is applied to a cluster, the EVC settings are lost, which causes loss of EVC functionalities. For example, unmasked CPUs can be exposed to workloads.

Workaround: Reconfigure the relevant EVC baseline on cluster to recover the EVC settings.

Using a host profile that defines a core dump partition in vCenter Server 7.0 results in an error

In vCenter Server 7.0, configuring and managing a core dump partition in a host profile is not available. Attempting to apply a host profile that defines a core dump partition, results in the following error: `No valid coredump partition found.`

Workaround: None. In vCenter Server 7.0., Host Profiles supports only file-based core dumps.

If you run the ESXCLI command to unload the firewall module, the hostd service fails and ESXi hosts lose connectivity

If you automate the firewall configuration in an environment that includes multiple ESXi hosts, and run the ESXCLI command `esxcli network firewall unload` that destroys filters and unloads the firewall module, the hostd service fails and ESXi hosts lose connectivity.

Workaround: Unloading the firewall module is not recommended at any time. If you must unload the firewall module, use the following steps:

1. Stop the hostd service by using the command:
   `/etc/init.d/hostd stop.`
2. Unload the firewall module by using the command:
   `esxcli network firewall unload.`
3. Perform the required operations.
4. Load the firewall module by using the command:
   `esxcli network firewall load.`
5. Start the hostd service by using the command:
   `/etc/init.d/hostd start.`

vSphere Storage vMotion operations might fail in a vSAN environment due to an unauthenticated session of the Network File Copy (NFC) manager

Migrations to a vSAN datastore by using vSphere Storage vMotion of virtual machines that have at least one snapshot and more than one virtual disk with different storage policy might fail. The issue occurs due to an unauthenticated session of the NFC manager because the Simple Object Access Protocol (SOAP) body exceeds the allowed size.

Workaround: First migrate the VM home namespace and just one of the virtual disks. After the operation completes, perform a disk only migration of the remaining 2 disks.

Changes in the properties and attributes of the devices and storage on an ESXi host might not persist after a reboot

If the device discovery routine during a reboot of an ESXi host times out, the jumpstart plug-in might not receive all configuration changes of the devices and storage from all the registered devices on the host. As a result, the process might restore the properties of some devices or storage to the default values after the reboot.

Workaround: Manually restore the changes in the properties of the affected device or storage.

If you use a beta build of ESXi 7.0, ESXi hosts might fail with a purple diagnostic screen during some lifecycle operations

If you use a beta build of ESXi 7.0, ESXi hosts might fail with a purple diagnostic screen during some lifecycle operations such as unloading a driver or switching between ENS mode and native driver mode. For example, if you try to change the ENS mode, in the backtrace you see an error message similar to: `case ENS::INTERRUPT::NoVM_DeviceStateWithGracefulRemove hit BlueScreen: ASSERT bora/vmkernel/main/dlmalloc.c:2733` This issue is specific for beta builds and does not affect release builds such as ESXi 7.0.

Workaround: Update to ESXi 7.0 GA.

You cannot create snapshots of virtual machines due to an error that a digest operation has failed

A rare race condition when an All-Paths-Down (APD) state occurs during the update of the Content Based Read Cache (CBRC) digest file might cause inconsistencies in the digest file. As a result, you cannot create virtual machine snapshots. You see an error such as `An error occurred while saving the snapshot: A digest operation has failed` in the backtrace.

Workaround: Power cycle the virtual machines to trigger a recompute of the CBRC hashes and clear the inconsistencies in the digest file.

If you upgrade your ESXi hosts to version 7.0 Update 3, but your vCenter Server is of an earlier version, Trusted Platform Module (TPM) attestation of the ESXi hosts fails

If you upgrade your ESXi hosts to version 7.0 Update 3, but your vCenter Server is of an earlier version, and you enable TPM, ESXi hosts fail to pass attestation. In the vSphere Client, you see the warning Host TPM attestation alarm. The Elliptic Curve Digital Signature Algorithm (ECDSA) introduced with ESXi 7.0 Update 3 causes the issue when vCenter Server is not of version 7.0 Update 3.

Workaround: Upgrade your vCenter Server to 7.0 Update 3 or acknowledge the alarm.

You see warnings in the boot loader screen about TPM asset tags

If a TPM-enabled ESXi host has no asset tag set on, you might see idle warning messages in the boot loader screen such as:

```
Failed to determine TPM asset tag size: Buffer too smallFailed to measure asset tag into TPM: Buffer too small
```

Workaround: Ignore the warnings or set an asset tag by using the command `$ esxcli hardware tpm tag set -d`

The sensord daemon fails to report ESXi host hardware status

A logic error in the IPMI SDR validation might cause `sensord` to fail to identify a source for power supply information. As a result, when you run the command `vsish -e get /power/hostStats`, you might not see any output.

Workaround: None

If an ESXi host fails with a purple diagnostic screen, the netdump service might stop working

In rare cases, if an ESXi host fails with a purple diagnostic screen, the netdump service might fail with an error such as `NetDump FAILED: Couldn't attach to dump server at IP x.x.x.x.`

Workaround: Configure the VMkernel core dump to use local storage.

You see frequent VMware Fault Domain Manager (FDM) core dumps on multiple ESXi hosts

In some environments, the number of datastores might exceed the FDM file descriptor limit. As a result, you see frequent core dumps on multiple ESXi hosts indicating FDM failure.

Workaround: Increase the FDM file descriptor limit to 2048. You can use the setting `das.config.fdm.maxFds` from the vSphere HA advanced options in the vSphere Client. For more information, see Set Advanced Options.

Virtual machines on a vSAN cluster with enabled NSX-T and a converged vSphere Distributed Switch (CVDS) in a VLAN transport zone cannot power on after a power off

If a secondary site is 95% disk full and VMs are powered off before simulating a secondary site failure, during recovery some of the virtual machines fail to power on. As a result, virtual machines become unresponsive. The issue occurs regardless if site recovery includes adding disks or ESXi hosts or CPU capacity.

Workaround: Select the virtual machines that do not power on and change the network to VM Network from Edit Settings on the VM context menu.

ESXI hosts might fail with a purple diagnostic screen with an error Assert at bora/modules/vmkernel/vmfs/fs6Journal.c:835

In rare cases, for example when running SESparse tests, the number of locks per transaction in a VMFS datastore might exceed the limit of 50 for the `J6_MAX_TXN_LOCKACTIONS` parameter. As a result, ESXi hosts might fail with a purple diagnostic screen with an error `Assert at bora/modules/vmkernel/vmfs/fs6Journal.c:835`.

Workaround: None

If you modify the netq_rss_ens parameter of the nmlx5_core driver, ESXi hosts might fail with a purple diagnostic screen

If you try to enable the `netq_rss_ens` parameter when you configure an enhanced data path on the `nmlx5_core` driver, ESXi hosts might fail with a purple diagnostic screen. The `netq_rss_ens` parameter, which enables NetQ RSS, is disabled by default with a value of `0`.

Workaround: Keep the default value for the `netq_rss_ens` module parameter in the `nmlx5_core` driver.

ESXi might terminate I/O to NVMeOF devices due to errors on all active paths

Occasionally, all active paths to NVMeOF device register I/O errors due to link issues or controller state. If the status of one of the paths changes to Dead, the High Performance Plug-in (HPP) might not select another path if it shows high volume of errors. As a result, the I/O fails.

Workaround: Disable the configuration option **/Misc/HppManageDegradedPaths** to unblock the I/O.

Upgrade to ESXi 7.0 Update 3 might fail due to changed name of the inbox i40enu network driver

Starting with vSphere 7.0 Update 3, the inbox i40enu network driver for ESXi changes name back to i40en. The i40en driver was renamed to i40enu in vSphere 7.0 Update 2, but the name change impacted some upgrade paths. For example, rollup upgrade of ESXi hosts that you manage with baselines and baseline groups from 7.0 Update 2 or 7.0 Update 2a to 7.0 Update 3 fails. In most cases, the i40enu driver upgrades to ESXi 7.0 Update 3 without any additional steps. However, if the driver upgrade fails, you cannot update ESXi hosts that you manage with baselines and baseline groups. You also cannot use host seeding or a vSphere Lifecycle Manager single image to manage the ESXi hosts. If you have already made changes related to the i40enu driver and devices in your system, before upgrading to ESXi 7.0 Update 3, you must uninstall the i40enu VIB or Component on ESXi, or first upgrade ESXi to ESXi 7.0 Update 2c.

Workaround: For more information, see VMware knowledge base article 85982.

SSH access fails after you upgrade to ESXi 7.0 Update 3d

After you upgrade to ESXi 7.0 Update 3d, SSH access might fail in certain conditions due to an update of OpenSSH to version 8.8.

Workaround: For more information, see VMware knowledge base article 88055.

USB device passthrough from ESXi hosts to virtual machines might fail

A USB modem device might simultaneously claim multiple interfaces by the VMkernel and block the device passthrough to VMs.

Workaround: You must apply the USB.quirks advanced configuration on the ESXi host to ignore the NET interface from VMkernel and allow the USB modem to passthrough to VMs. You can apply the configuration in 3 alternative ways:

1. Access the ESXi shell and run the following command: `esxcli system settings advanced set -o /USB/quirks -s 0xvvvv:0xpppp:0:0xffff:UQ_NET_IGNORE | |- Device Product ID |------- Device Vendor ID`
   For example, for the Gemalto M2M GmbH Zoom 4625 Modem(`vid:pid/1e2d:005b`), you can have the command `esxcli system settings advanced set` **-o** `/USB/quirks -s 0x1e2d:0x005b:0:0xffff:UQ_NET_IGNORE`
   Reboot the ESXi host.
2. Set the advanced configuration from the vSphere Client or the vSphere Web Client and reboot the ESXi host.
3. Use a Host Profile to apply the advanced configuration.

For more information on the steps, see VMware knowledge base article 80416.

HTTP requests from certain libraries to vSphere might be rejected

The HTTP reverse proxy in vSphere 7.0 enforces stricter standard compliance than in previous releases. This might expose pre-existing problems in some third-party libraries used by applications for SOAP calls to vSphere.

If you develop vSphere applications that use such libraries or include applications that rely on such libraries in your vSphere stack, you might experience connection issues when these libraries send HTTP requests to VMOMI. For example, HTTP requests issued from vijava libraries can take the following form:

```
POST /sdk HTTP/1.1
SOAPAction
Content-Type: text/xml; charset=utf-8
User-Agent: Java/1.8.0_221
```

The syntax in this example violates an HTTP protocol header field requirement that mandates a colon after SOAPAction. Hence, the request is rejected in flight.

Workaround: Developers leveraging noncompliant libraries in their applications can consider using a library that follows HTTP standards instead. For example, developers who use the vijava library can consider using the latest version of the yavijava library instead.

You might see a dump file when using Broadcom driver lsi_msgpt3, lsi_msgpt35 and lsi_mr3

When using the lsi_msgpt3, lsi_msgpt35 and lsi_mr3 controllers, there is a potential risk to see dump file lsuv2-lsi-drivers-plugin-util-zdump. There is an issue when exiting the storelib used in this plugin utility. There is no impact on ESXi operations, you can ignore the dump file.

Workaround: You can safely ignore this message. You can remove the lsuv2-lsi-drivers-plugin with the following command:

```
esxcli software vib remove -n lsuv2-lsiv2-drivers-plugin
```

You might see reboot is not required after configuring SR-IOV of a PCI device in vCenter, but device configurations made by third party extensions might be lost and require reboot to be re-applied.

In ESXi 7.0, SR-IOV configuration is applied without a reboot and the device driver is reloaded. ESXi hosts might have third party extensions perform device configurations that need to run after the device driver is loaded during boot. A reboot is required for those third party extensions to re-apply the device configuration.

Workaround: You must reboot after configuring SR-IOV to apply third party device configurations.

vSphere Client Issues

BIOS manufacturer displays as "--" in the vSphere Client

In the vSphere Client, when you select an ESXi host and navigate to **Configure** > **Hardware** > **Firmware**, you see `--` instead of the BIOS manufacturer name.

Workaround: For more information, see VMware knowledge base article 88937.

vSAN Issues

PR 2962316: vSAN File Service does not support NFSv4 delegations

vSAN File Service does not support NFSv4 delegations in this release.

Workaround: None

PR 3235496: Applications on a vSAN cluster become intermittently unresponsive

If the advanced option `preferHT` is enabled on an AMD server in a vSAN cluster, the virtual CPUs of a virtual machine run on the same last level cache. When the virtual CPUs are all very busy and an NVMe thread to handle I/Os happens to run also on the same last level cache, the NVMe thread takes very long to complete, because it competes for CPU resources with the busy VMs. As a result, the I/O latency is very high and might lead to intermittent unresponsiveness of storage and applications on the vSAN cluster. In the backlog, you see errors such as `Lost access to volume <uuid> due to connectivity issues. Recovery attempt is in progress and outcome will be reported shortly.`

Workaround: Use the command `esxcli system settings advanced set -o /Misc/vmknvmeCwYield -I 0` to avoid competition between the NVMe completion queue and busy virtual CPUs.

VMware ESXi 7.0 Update 3o Release Notes

This document contains the following sections

- Introduction
- What's New
- Earlier Releases of ESXi 7.0
- Product Support Notices
- Patches Contained in This Release
- Patch Download and Installation
- Resolved Issues
- Known Issues

Introduction

VMware ESXi 7.0 Update 3o | 28 SEP 2023 | Build 22348816
Check for additions and updates to these release notes.

IMPORTANT: If your source system contains hosts of versions between ESXi 7.0 Update 2 and Update 3c, and Intel drivers, before upgrading to ESXi 7.0 Update 3o, see the What's New section of the VMware vCenter Server 7.0 Update 3c Release Notes, because all content in the section is also applicable for vSphere 7.0 Update 3o. Also, see the related VMware knowledge base articles: 86447, 87258, and 87308.

What's New

- ESXi 7.0 Update 3o adds support for vSphere Quick Boot to multiple servers, including:
  - Dell
    - PowerEdge XR4510c
    - PowerEdge XR4520c
    - PowerEdge XR5610
    - PowerEdge XR7620
    - PowerEdge XR8620t
    - R6615 vSAN Ready Node
    - R7615 vSAN Ready Node
    - VxRail VD-4510c
    - VxRail VD-4520c
  - Lenovo
    - ThinkSystem SR635 V3
    - ThinkSystem SR645 V3
    - ThinkSystem ST650 V3
    - ThinkSystem SR655 V3
  - HPE
    - Alletra 4120
    - Cray XD220v
    - ProLiant DL320 Gen11
    - ProLiant DL380a Gen11
    - ProLiant DL560 Gen11
    - ProLiant ML110 Gen11
    - ProLiant DL360 Gen11
    - ProLiant DL380 Gen11
    - ProLiant ML350 Gen11
- ESXi 7.0 Update 3o adds support for vSphere Quick Boot to several drivers, including:
  - Intel
    - QuickAssist Technology (QAT)
    - Dynamic Load Balancer (DLB)
  - Cisco
    - NENIC_ENS

  For the full list of supported servers and drivers, see the VMware Compatibility Guide.

Earlier Releases of ESXi 7.0

New features, resolved, and known issues of ESXi are described in the release notes for each release. Release notes for earlier releases of ESXi 7.0 are:

- VMware ESXi 7.0, ESXi 7.0 Update 3n Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3m Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3l Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3k Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3j Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3i Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3g Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3f Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2a Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2 Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1b Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1a Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1 Release Notes
- VMware ESXi 7.0, ESXi 7.0b Release Notes

For internationalization, compatibility, and open source components, see the VMware vSphere 7.0 Release Notes.

Product Support Notices

Support for spaces in organizational units (OUs) names: With ESXi 7.0 Update 3o, vSAN File Service supports spaces in organizational units (OUs) names.

Patches Contained in This Release

This release of ESXi 7.0 Update 3o delivers the following patches:

Build Details

Download Filename:	VMware-ESXi-7.0U3o-22348816-depot.zip
Build:	22348816
Download Size:	574.5 MB
md5sum:	2dc3fe97405d94a12c3a7b14570e24c1
sha256checksum:	42594bd42b9cf2f7d002780d8fee9062a61567a9f3f1a0675726a6f29075d607
Host Reboot Required:	Yes
Virtual Machine Migration or Shutdown Required:	Yes

Components

Component	Bulletin	Category	Severity
ESXi Component - core ESXi VIBs	ESXi_7.0.3-0.105.22348816	Bugfix	Critical
ESXi Install/Upgrade Component	esx-update_7.0.3-0.105.22348816	Bugfix	Critical
VMware Native AHCI Driver	VMware-ahci_2.0.11-2vmw.703.0.105.22348816	Bugfix	Critical
SMARTPQI LSU Management Plugin	Microchip-smartpqiv2-plugin_1.0.0-9vmw.703.0.105.22348816	Bugfix	Critical
Non-Volatile memory controller driver	VMware-NVMe-PCIe_1.2.3.16-3vmw.703.0.105.22348816	Bugfix	Critical
Avago (LSI) Native 12Gbps SAS MPT Driver	Broadcom-lsi-msgpt3_17.00.12.00-2vmw.703.0.105.22348816	Bugfix	Critical
Intel NVME Driver with VMD Technology	Intel-Volume-Mgmt-Device_2.7.0.1157-3vmw.703.0.105.22348816	Bugfix	Critical
ESXi Component - core ESXi VIBs	ESXi_7.0.3-0.100.22348808	Security	Critical
ESXi Install/Upgrade Component	esx-update_7.0.3-0.100.22348808	Security	Critical
ESXi Tools Component	VMware-VM-Tools_12.2.6.22229486-22348808	Security	Critical

IMPORTANT:

- Starting with vSphere 7.0, VMware uses components for packaging VIBs along with bulletins. The `ESXi` and `esx-update` bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.
- When patching ESXi hosts by using VMware Update Manager from a version prior to ESXi 7.0 Update 2, it is strongly recommended to use the rollup bulletin in the patch baseline. If you cannot use the rollup bulletin, be sure to include *all* of the following packages in the patching baseline. If the following packages are not included in the baseline, the update operation fails:
  - VMware-vmkusb_0.1-1vmw.701.0.0.16850804 or higher
  - VMware-vmkata_0.1-1vmw.701.0.0.16850804 or higher
  - VMware-vmkfcoe_1.0.0.2-1vmw.701.0.0.16850804 or higher
  - VMware-NVMeoF-RDMA_1.0.1.2-1vmw.701.0.0.16850804 or higher

Rollup Bulletin

This rollup bulletin contains the latest VIBs with all the fixes after the initial release of ESXi 7.0.

Bulletin ID	Category	Severity	Details
ESXi70U3o-22348816	Bugfix	Critical	Security and Bugfix
ESXi70U3so-22348808	Security	Critical	Security only

Image Profiles

VMware patch and update releases contain general and critical image profiles. Application of the general release image profile applies to new bug fixes.

Image Profile Name
ESXi-7.0U3o-22348816-standard
ESXi-7.0U3o-22348816-no-tools
ESXi-7.0U3so-22348808-standard
ESXi-7.0U3so-22348808-no-tools

ESXi Image

Name and Version	Release Date	Category	Details
ESXi7.0U3o - 22348816	SEP 28 2023	Bugfix	Security and Bugfix image
ESXi7.0U3so - 22348808	SEP 28 2023	Security	Security only image

For information about the individual components and bulletins, see the Resolved Issues section.

Patch Download and Installation

Download this patch from the Broadcom Support Portal.

For download instructions for earlier releases, see Download Broadcom products and software.

In vSphere 7.x, the Update Manager plug-in, used for administering vSphere Update Manager, is replaced with the Lifecycle Manager plug-in. Administrative operations for vSphere Update Manager are still available under the Lifecycle Manager plug-in, along with new capabilities for vSphere Lifecycle Manager.

The typical way to apply patches to ESXi 7.x hosts is by using the vSphere Lifecycle Manager. For details, see About vSphere Lifecycle Manager and vSphere Lifecycle Manager Baselines and Images.

You can also update ESXi hosts without using the Lifecycle Manager plug-in, and use an image profile instead. To do this, you must manually download the patch offline bundle ZIP file.

For details, see How to Download a ZIP file for ESXi Patches and Updates, Upgrading Hosts by Using ESXCLI Commands, and the VMware ESXi Upgrade guide.

Resolved Issues

The resolved issues are grouped as follows:

ESXi_7.0.3-0.105.22348816

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs Included	• VMware_bootbank_gc_7.0.3-0.105.22348816 • VMware_bootbank_native-misc-drivers_7.0.3-0.105.22348816 • VMware_bootbank_vsanhealth_7.0.3-0.105.22348816 • VMware_bootbank_crx_7.0.3-0.105.22348816 • VMware_bootbank_esx-xserver_7.0.3-0.105.22348816 • VMware_bootbank_vdfs_7.0.3-0.105.22348816

	• VMware_bootbank_cpu-microcode_7.0.3-0.105.22348816 • VMware_bootbank_esx-base_7.0.3-0.105.22348816 • VMware_bootbank_vsan_7.0.3-0.105.22348816 • VMware_bootbank_esxio-combiner_7.0.3-0.105.22348816 • VMware_bootbank_esx-ui_2.11.2-21988676 • VMware_bootbank_bmcal_7.0.3-0.105.22348816 • VMware_bootbank_esx-dvfilter-generic-fastpath_7.0.3-0.105.22348816 • VMware_bootbank_trx_7.0.3-0.105.22348816
PRs Fixed	3244098, 3216958, 3245763, 3242021, 3246132, 3253205, 3256804, 3239170, 3251981, 3215370, 3117615, 3248478, 3252676, 3235496, 3238026, 3236064, 3224739, 3224306, 3223755, 3216958, 3233958, 3185125, 3219264, 3221620, 3218835, 3185560, 3221099, 3211625, 3221860, 3228586, 3224604, 3223539, 3222601, 3217258, 3213041, 3216522, 3221591, 3216389, 3220004, 3217633, 3216548, 3216449, 3156666, 3181574, 3180746, 3155476, 3211807, 3154090, 3184008, 3183519, 3183519, 3209853, 3100552, 3187846, 3113263, 3176350, 3185827, 3095511, 3184425, 3186351, 3186367, 3154090, 3158524, 3181601, 3180391, 3180283, 3184608, 3181774, 3155476, 3163361, 3182978, 3184368, 3160456, 3164575, 3181901, 3184871, 3166818, 3157195, 3164355, 3163271, 3112194, 3161690, 3261925, 3178589, 3178721, 3162963, 3168950, 3159168, 3158491, 3158866, 3096769, 3165374, 3122037, 3098760, 3164439, 3161473, 3162790, 3100030, 3096974, 3161473, 3165651, 3083007, 3118240, 3151076, 3118402, 3160480, 3156627, 3158531, 3162499, 3158512, 3053430, 3153395, 3117615, 3099192, 3158508, 3115870, 3119834, 3158220, 3110401, 2625439, 3099357, 3152811, 3108979, 3120165
CVE numbers	N/A

The ESXi and esx-update bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.

Updates the `gc`, `native-misc-drivers`, `vsanhealth`, `crx`, `esx-xserver`, `vdfs`, `cpu-microcode`, `esx-base`, `vsan`, `esxio-combiner`, `esx-ui`, `bmcal`, `esx-dvfilter-generic-fastpath` and `trx` VIBs to resolve the following issues:

PR 3253205: Static IPv6 gateway disappears in 18 hours

If you configure a static IPv6 gateway address in your vSphere environment, such gateways might no longer exist in up to 18 hours due to a timeout.

This issue is resolved in this release. The fix removes the existing timeout for static gateways.

PR 3272532: You see speed as Half Duplex after changing the speed from Auto to Full on a VMNIC

In some cases, length checks during the parsing of duplex TLVs in an environment with active Cisco Discovery Protocol (CDP) might fail. As a result, when you change the speed from **Auto** to **Full** on a physical NIC on peer devices you do not see the real duplex value in the TLV under the neighbor information, but the default Half Duplex value.

This issue is resolved in this release.

PR 3251981: An NFSv4.1 file might appear to be empty even though it contains data

When you open an existing NFSv4.1 file with write only access, if for some reason the NFS client opens again the same file with read only access, read operations from the client might return no data although the file is not empty.

This issue is resolved in this release.

PR 3116601: When you override the default gateway for the vSAN VMkernel adapter on an ESXi host, the vSphere HA agent on the host displays as inaccessible

In some cases, when you override the default gateway for the vSAN VMkernel adapter on an ESXi host, the Fault Domain Manager (FDM), which is the agent that vSphere HA deploys on ESX hosts, might stop receiving Internet Control Message Protocol (ICMP) pings. As a result, FDM might issue false cluster alarms that the vSphere HA agent on the host cannot reach some management network addresses of other hosts.

This issue is resolved in this release.

PR 3251801: vSphere vMotion operation from a 6.7.x ESXi host with an Intel Ice Lake CPU fails with msg.checkpoint.cpucheck.fail

vSphere vMotion operations by using either the vSphere Client or VMware Hybrid Cloud Extension (HCX) from an Intel Ice Lake CPU host running ESXi 6.7.x fails with an error such as `msg.checkpoint.cpucheck.fail` . In the vSphere Client, you see a message that cpuid.PSFD is not supported on the target host. In HCX, you see a report such as `A general system error occurred: vMotion failed:` .

This issue is resolved in this release.

PR 3224739: You see alarms for dropped syslog messages

If the network throughput of your vSphere system does not align with the speed at which log messages are generated, some of the log messages sent to the remote syslog server might drop. As a result, in the vSphere Client you see host errors of type `Triggered Alarm` and in the logs, you see warnings such as `ALERT: vmsyslog logger xxxx:514 lost yyyy log messages` .

This issue is resolved in this release. The fix improves the network logging performance of the logging service to reduce the number of such lost log messages.

PR 3247027: If any failure occurs during a vSphere vMotion migration of NVIDIA virtual GPU (vGPU) VM, the destination ESXi host might fail with a purple diagnostic screen

In very rare cases, if any type of failure occurs during a vSphere vMotion migration of a vGPU VM, the vMotion operation is marked as a failure while a specific internal operation is in progress. As a result, the destination ESXi host might fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3095511: The SFCB service intermittently fails and generates "sfcb-vmware_bas-zdump" files on multiple ESXi hosts

In very rare cases, when the SFCB service tries to access an uninitialized variable, the service might fail with dump file such as `sfcb-vmware_bas-zdump.000` . The issue occurs because accessing an uninitialized variable can cause the SFCB process to keep requesting memory until it exceeds the heap allocation.

This issue is resolved in this release.

PR 3256804: File server loses connectivity after failover when running vSAN File Service on NSX overlay network

If vSAN File Service is running on an NSX overlay network, the file server might lose connectivity after it fails over from one agent VM to another agent VM. The file server can failover when reconfiguring file service domain from such without Active Directory(AD) to such with AD, or if vSAN detects unhealthy behavior in the file server, file share, or AD server. If file server connectivity is lost after a failover, File Service clients cannot access the file share. The following health warning might be reported:

```
One or more DNS servers is not reachable.
```

This issue is resolved in this release.

PR 3217633: vSAN management service on the orchestration host malfunctions during vCenter restart

This issue can occur on vSAN clusters where vCenter is deployed. If multiple cluster shutdown operations are performed, the `/etc/vmware/vsan/vsanperf.conf` file on the orchestration host can contain two versions of the following management VM: `vc_vm_moIdvc_vm_moid`. These configuration options conflict with each other and can cause the vSAN management service to malfunction.

This issue is resolved in this release.

PR 3224306: When you change the ESXi syslog setting syslog.global.logDir, if syslog.global.logDirUnique is active, you might see 2 levels of <hostname> subdir under the logdir path

After upgrading an ESXi host to 7.0 Update 3c and later, if you change the syslog setting `syslog.global.logDir` and the `syslog.global.logDirUnique` setting is active, you might see 2 levels of `<hostname>` subdirs under the `logdir` path on the host. The `syslog.global.logDirUnique` setting is useful if the same NFS directory is configured as the `Syslog.global.LogDir` by multiple ESXi hosts, as it creates a subdirectory with the name of the ESXi host under `logdir`.

This issue is resolved in this release.

PR 3223755: ESXi syslog daemon fails to resume transmitting logs to the configured SSL remote syslog server once a drop in the network connectivity restores

If a remote SSL syslog server temporarily loses connectivity, the ESXi syslog daemon might fail to resume transmitting logs after connectivity restores and you must restart the service to re-activate transmissions. The issue occurs due to some unhandled exceptions while the ESXi syslog daemon tries to restore connection to the SSL remote syslog server.

This issue is resolved in this release. The fix adds a generic catch for all unhandled exceptions.

PR 3185536: vSAN cluster remediation error after vCenter upgrade to 7.0 Update 3

When you upgrade vCenter from version 6.5.x to 7.0 Update 3, and reconfigure the vSAN cluster, a vSAN cluster remediation is triggered, but in some cases fails.

This issue is resolved in this release.

PR 3110401: The Explicit Congestion Notification (ECN) setting is not persistent on ESXi host reboot

ECN, specified in RFC 3168, allows a TCP sender to reduce the transmission rate to avoid packet drops and is activated by default. However, if you change the default setting, or manually deactivate ECN, such changes to the ESXi configuration might not persist after a reboot of the host.

This issue is resolved in this release.

PR 3153395: Upon refresh, some dynamic firewalls rules might not persist and lead to vSAN iSCSI Target service failure

If you frequently run the command `esxcli network firewall refresh`, a race condition might cause some dynamic firewalls rules to be removed upon refresh or load. As a result, some services such as the vSAN iSCSI Target daemon, which provides vSAN storage with iSCSI protocol, might fail.

This issue is resolved in this release.

PR 3096769: You see high latency for VM I/O operations in a vSAN cluster with Unmap activated

This issue affects vSAN clusters with Unmap activated. A problem in Unmap handling in LSOM creates log congestion. The log congestion can cause high VM I/O latency.

This issue is resolved in this release.

PR 3163361: The Audit Record Storage Capacity parameter does not persist across ESXi host reboots

After an ESXi host reboot, you see the **Audit Record Storage Capacity** parameter restored to the default value of 4 MiB, regardless of any previous changes.

This issue is resolved in this release.

PR 3162496: If the Internet Control Message Protocol (ICMPA) is not active, ESXi host reboot might take long after upgrading to vSphere 8.0 and later

If ICMPA is not active on the NFS servers in your environment, after upgrading your system to vSphere 8.0 and later, ESXi hosts reboot might take an hour to complete, because restore operations for NFS datastores fail. NFS uses the `vmkping` utility to identify reachable IPs of the NFS servers before executing a mount operation and when ICMP is not active, mount operations fail.

This issue is resolved in this release. To remove dependency on the ICMP protocol to find reachable IPs, the fix adds socket APIs to ensure that IPs on a given NFS server are available.

PR 3220004: VBS-enabled Windows VMs might fail with a blue diagnostic screen when an ESXi host is under memory pressure

Windows VMs with virtualization-based security (VBS) enabled might intermittently fail with a blue diagnostic screen during memory-heavy operations such as deleting snapshots or consolidating disks. The BSOD has the following signature:

```
DRIVER_VERIFIER_DMA_VIOLATION (e6)
An illegal DMA operation was attempted by a driver being verified.
```

Arguments:

```
Arg1: 0000000000000026, IOMMU detected DMA violation.
Arg2: 0000000000000000, Device Object of faulting device.
Arg3: xxxxxxxxxxxxxxxx, Faulting information (usually faulting physical address).
Arg4: 0000000000000008, Fault type (hardware specific).
```

This issue is resolved in this release.

PR 3162905: ESXi hosts might intermittently disconnect from vCenter in case of memory outage

In rare cases, if vCenter fails to allocate or transfer active bitmaps due to an alert for insufficient memory for any reason, the hostd service might repeatedly fail and you cannot reconnect the host to the vCenter.

This issue is resolved in this release. The fix makes sure that in such cases you see an error rather than the hostd service failure.

PR 3108979: Staging ESXi patches and ESXi upgrade tasks might become indefinitely unresponsive due to a log buffer limit

If a large string or log exceed the python log buffer limit of 16K, the logger becomes unresponsive. As a result, when you stage ESXi patches on a host by using the vSphere Client, the process responsible for completing the staging task on ESXi might become indefinitely unresponsive. The task times out and reports an error. The issue occurs also when you remediate ESXi hosts by using a patch baseline.

This issue is resolved in this release. The fix breaks the large input string into smaller chunks for logging.

PR 3219264: vSAN precheck for maintenance mode or disk decommission doesn't list objects that might lose accessibility

This issue affects objects with resyncing components, and some components reside on a device to be removed or placed into maintenance mode. When you run a precheck with the **No-Action** option, the precheck does not evaluate the object correctly to report it in the `inaccessibleObjects` list.

This issue is resolved in this release. Precheck includes all affected objects in the `inaccessibleObjects` list.

PR 3186545: Vulnerability scans might report the HTTP TRACE method on vCenter ports 9084 and 9087 as vulnerable

Some third-party tools for vulnerability scans might report the HTTP TRACE method on vCenter ports 9084 and 9087 as vulnerable.

This issue is resolved in this release.

PR 3221591: ESXi NVMe/TCP initiator fails to recover paths after target failure recovery

When a NVMe/TCP target recovers from a failure, ESXi cannot recover the path.

This issue is resolved in this release.

PR 3186351: You see an override flag of NIC teaming, security, or traffic shaping policy on a portgroup unexpectedly enabled post an ESXi host reboot

In some cases, a networking configuration might not persist in the ESXi ConfigStore and you see an override flag of NIC teaming, security, or traffic shaping policy on a portgroup unexpectedly enabled post an ESXi host reboot.

This issue is resolved in this release.

PR 3162790: The sfcb daemon might fail with a core dump while installing a third-party CIM provider

The sfcb daemon might try to access already freed memory when registering a CIM provider and fail with a core dump while installing a third-party CIM provider, such as Dell OpenManage Server Administrator for example.

This issue is resolved in this release.

PR 3157195: ESX hosts might fail with a purple diagnostic screen and an error NMI IPI: Panic requested by another PCPU

The resource pool cache is a VMFS specific volume level cache that stores the resource clusters corresponding to the VMFS volume. While searching for priority clusters, the cache flusher workflow iterates through a large list of cached resource clusters, which can cause lockup of the physical CPUs. As a result, ESX hosts might fail with a purple diagnostic screen. In the `logDump` file, you see an error such as:

```
^[[7m2022-10-22T07:56:47.322Z cpu13:2101160)WARNING: Heartbeat: 827: PCPU 0 didn't have a heartbeat for 7 seconds, timeout is 14, 1 IPIs sent; *may* be locked up.^[[0m^
```

```
[[31;1m2022-10-22T07:56:47.322Z cpu0:2110633)ALERT: NMI: 710: NMI IPI: RIPOFF(base):RBP:CS
```

This issue is resolved in this release.

PR 3230493: If a delta sync runs while the target vSphere Replication server is not active, Windows virtual machines might become unresponsive

If the target Sphere Replication server is not active during a delta sync, the synchronization process cannot complete and Windows virtual machines become unresponsive.

This issue is resolved in this release. The fix makes sure that no delta sync jobs start when a Sphere Replication server is not active.

PR 3122037: ESXi ConfigStore database fills up and writes fail

Stale data related to block devices might not be deleted in time from the ESXi ConfigStore database and cause an out of space condition. As a result, write operations to ConfigStore start to fail. In the backtrace, you see logs such as:

```
2022-12-19T03:51:42.733Z cpu53:26745174)WARNING: VisorFSRam: 203: Cannot extend visorfs file /etc/vmware/configstore/current-store-1-journal because its ramdisk (configstore) is full .
```

This issue is resolved in this release.

PR 3246132: You see a system clock drift on an ESXi host after synchronization with the NTP server fails

If connectivity between the NTP server and an ESXi host is delayed for some reason, the system clock on the ESXi host might experience a drift. When you run the `vsish` command `vsish -e get /system/ntpclock/clockData` , you might see a large negative value for the `adjtime` field. For example:

```
NTP clock data {
...  adjtime() (usec):-309237290312 <<<<<<
...
}
```

This issue is resolved in this release.

PR 3185560: vSphere vMotion operations for virtual machines with swap files on a vSphere Virtual Volumes datastore intermittently fail after a hot extend of the VM disk

vSphere vMotion operations for virtual machines with swap files on a vSphere Virtual Volumes datastore might fail under the following circumstances:

A VM that runs on ESXi host A is migrated to ESXi host B, then the VM disk is hot extended, and the VM is migrated back to ESXi host A. The issue occurs due to stale statistics about the swap virtual volume.

This issue is resolved in this release.

PR 3236207: You cannot unmount an NFS v3 datastore from a vCenter system because the datastore displays as inaccessible

While unmounting an NFSv3 datastore from a vCenter system by using either the vSphere Client or ESXCLI, you might see the datastore either as inaccessible, or get an `Unable to Refresh` error. The issue occurs when a hostd cache refresh happens before NFS deletes the mount details from ConfigStore, which creates a rare race condition.

This issue is resolved in this release.

PR 3236064: Compliance or remediation scans by using vSphere Lifecycle Manager might take long on ESXi hosts with a large number of datastores

Compliance or remediation scans by using vSphere Lifecycle Manager include an upgrade precheck that lists all volumes attached to an ESXi host, their free space, versions, and other details. If a host has many datastores attached, each with a large capacity, the precheck can take long. The time is multiplied by the number of baselines attached to the cluster or host.

This issue is resolved in this release. If you already face the issue, disconnect the attached datastores while performing the remediation or compliance scans and reattach them after the operations complete.

PR 3245763: During a vSphere vMotion operation, destination ESXi hosts with a Distributed Firewall (DFW) enabled might fail with a purple diagnostic screen

If the destination host in a vSphere vMotion operation has a DFW enabled, a rare race condition might cause the host to fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3158866: Virtual machines might become unresponsive during VMFS volume expansion due to a Logical Volume Manager (LVM) check

If a VMFS volume expansion operation happens during a LVM probe to update volume attributes, such as the size of the VMFS partition backing of the VMFS volume, the current size of the VMFS volume might not match the LVM metadata on the disk. As a result, LVM marks such a volume offline and virtual machines on that volume become unresponsive.

This issue is resolved in this release. The fix improves Input Output Control (IOCTL) to speed up the update of device attributes and avoid such cases.

PR 3152717: vSphere Auto Deploy workflows might fail after an upgrade to vCenter Server 7.0 Update 3j or later

Due to a networking issue in reverse proxy configuration environments, vSphere Auto Deploy workflows might fail after an upgrade to vCenter Server 7.0 Update 3j or later. In the ESXi management console and in the `/var/log/vmware/rbd/rbd-cgi.log file` you see an HTTP client error.

This issue is resolved in this release. The fix makes sure Auto Deploy workflows run successfully in reverse proxy configuration environments.

PR 3185125: Virtual SLIT table not populated for the guest OS when using sched.nodeX.affinity

When you specify virtual NUMA node affinity, the vSLIT table might not be populated and you see the following error in `vmware.log : vSLIT: NumaGetLatencyInfo failed with status: 195887107.`

This happens when setting node affinity as follows:

```
numa.slit.enable = "TRUE"

sched.node0.affinity = 0

sched.node1.affinity = 1

...sched.nodeN.affinity = N
```

This issue is resolved in this release. If you already face the issue, specify VCPU affinity to physical CPUs on the associated NUMA nodes, instead of node affinity.

For example:

```
numa.slit.enable = "TRUE"

sched.vcpu0.affinity = "0-7"

sched.vcpu1.affinity = "0-7"

...sched.vcpuN.affinity = "Y-Z"
```

PR 3181774: You do not see an error when you attach a CBT enabled FCD to a VM with CBT disabled

Attaching a First Class Disk (FCD) with Changed Block Tracking (CBT) to a VM with CBT disabled does not throw a detailed error, but the operation cannot take effect. In the backtrace, you might see an error message such as `InvalidState` , which is generic and does not provide details on the issue.

This issue is resolved in this release. The fix adds the error message `Cannot attach a CBT enabled fcd: {path} to CBT disabled VM.` to the logs of the hostd service and adds a status message for the task in the vSphere Client.

PR 3185827: You see trap files in a SNMP directory under /var/spool even though SNMP is not enabled

After the hostd service starts, for example after an ESXi host reboot, it might create a SNMP directory under `/var/spool` and you see many `.trp` files to pile in this directory.

This issue is resolved in this release. The fix makes sure that the directory `/var/spool/snmp` exists only when SNMP is enabled.

PR 3082867: An ESXi host might fail with a purple diagnostic screen after a replicated virtual machine migrates to the host

In some environments, when a replicated virtual machine migrates to a certain ESXi host, during a full sync, some `SCSI WRITE` commands might target address ranges past the end of the transfer map. As a result, the ESXi host might fail with a purple diagnostic screen and a backtrace such as:

```
#0 DLM_free (msp=0x43238f2c9cc0, mem=mem@entry=0x43238f6db860, allowTrim=allowTrim@entry=1
'\001') at bora/vmkernel/main/dlmalloc.c:4924

#1 0x000041802a151e01 in Heap_Free (heap=0x43238f2c9000, mem=<optimized out>) at bora/
vmkernel/main/heap.c:4217
```

```
#2 0x000041802a3b0fa1 in BitVector_Free (heap=<optimized out>, bv=<optimized out>) at
bora/vmkernel/util/bitvector.c:94

#3 0x000041802b9f4f3f in HbrBitmapFree (bitmap=<optimized out>) at bora/modules/vmkernel/
hbr_filter/hbr_bitmap.c:91
```

This issue is resolved in this release.

PR 3162499: During service insertion for NSX-managed workload VMs, some VMS might become intermittently unresponsive, and the virtual device might reset

During service insertion for NSX-managed workload VMs, a packet list might be reinjected from the input chain of one switchport to another switchport. In such cases, the source switchport does not correspond to the actual `portID` of the input chain and the virtual device does not get completion status for the transmitted frame. As a result, when you run a service insertion task, some VMs might become intermittently unresponsive due to network connectivity issues.

This issue is resolved in this release.

PR 3219441: You cannot send keys to a guest OS by using the browser console in the ESXi Host Client

In the ESXi Host Client, when you open the browser console of a virtual machine and select **Guest OS > Send keys**, when you select a key input, for example **Ctrl-Alt-Delete**, the selection is not sent to the guest OS.

This issue is resolved in this release.

PR 3209853: Windows VMs might fail with a blue diagnostic screen with 0x5c signature due to platform delays

Windows VMs might fail with a blue diagnostic screen with the following signature due to a combination of factors involving the Windows timer code and platform delays, such as storage or network delays:

`HAL_INITIALIZATION_FAILED (0x5c)` (This indicates that the HAL initialization failed.)

Arguments:

```
Arg1: 0000000000000115, HAL_TIMER_INITIALIZATION_FAILURE

Arg2: fffff7ea800153e0, Timer address

Arg3: 00000000000014da, Delta in QPC units (delta to program the timer with)

Arg4: ffffffffc0000001, invalid status code (STATUS_UNSUCCESSFUL)
```

Checks done by HPET timers in Windows might fail due to such platform delays and cause the issue.

This issue is resolved in this release.

PR 3178109: vSphere Lifecycle Manager compliance check fails with "An unknown error occurred while performing the operation"

The base ESXi image contains driver components that can be overridden by higher version async driver components packaged by an OEM add-on. If such a component is manually removed on a host, the compliance check of the vSphere Lifecycle Manager might fail unexpectedly. In the vSphere Client, you see errors such as `Host status is unknown` and `An unknown error occurred while performing the operation.`

This issue is resolved in this release.

PR 3180634: Performance of certain nested virtual machines on AMD CPUs might degrade

Nested virtual machines on AMD CPUs with operational systems such as Windows with virtualization-based security (VBS) might experience performance degradation, timeouts, or unresponsiveness due to an issue with the virtualization of AMD's Rapid Virtualization Indexing (RVI), also known as Nested Page Tables (NPT).

This issue is resolved in this release.

PR 3223539: Some vmnics might not be visible after an ESXi host reboot due to a faulty NVMe device

If an NVMe device fails during the attach phase, the NVMe driver disables the NVMe controller and resets the hardware queue resources. When you try to re-attach the device, a mismatch between the hardware and driver queue pointers might cause an IOMMU fault on the NVMe device, which leads to memory corruption and failure of the vmkdevmgr service. As a result, you do not see some vmnics in your network.

This issue is resolved in this release.

PR 3218835: When you disable or suspend vSphere Fault Tolerance, virtual machines might become unresponsive for about 10 seconds

When you disable or suspend vSphere FT, some virtual machines might take about 10 seconds to release vSphere FT resources. As a result, such VMs become temporarily unresponsive to network requests or console operations.

This issue is resolved in this release.

PR 3181901: ESXi host becomes unresponsive and you cannot put the host in Maintenance Mode or migrate VMs from that host

Asynchronous reads of metadata on a VMFS volume attached to an ESXi host might cause a race condition with other threads on the host and make the host unresponsive. As a result, you cannot put the host in Maintenance Mode or migrate VMs from that host.

This issue is resolved in this release.

PR 3156666: Packets with length less than 60 bytes might drop

An ESXi host might add invalid bytes, other than zero, to packets with less than 60 bytes. As a result, packets with such invalid bytes drop.

This issue is resolved in this release.

PR 3180283: When you migrate a VM with recently hot-added memory, an ESXi host might repeatedly fail with a purple diagnostic screen

Due to a race condition while the memory hotplug module recomputes the NUMA memory layout of a VM on a destination host after migration, an ESXi host might repeatedly fail with a purple diagnostic screen. In the backtrace, you see errors such as:

```
0x452900262cf0:[0x4200138fee8b]PanicvPanicInt@vmkernel#nover+0x327 stack: 0x452900262dc8,

```

This issue is resolved in this release.

PR 3100552: ESXi booting times out after five minutes and the host automatically reboots

During initial ESXi booting, when you see the **Loading VMware ESXi** progress bar, if the bootloader takes more than a total of five minutes to load all the boot modules before moving on to the next phase of booting, the host firmware times out the boot process and resets the system.

This issue is resolved in this release. With ESXi 7.0 Update 3o, the ESXi bootloader resets the five-minute timeout after each boot module loads.

PR 3184368: The durable name of a SCSI LUN might not be set

The durable name property for a SCSI-3 compliant device comes from pages `80h` and `83h` of the Vital Product Data (VPD) as defined by the T10 and SMI standards. To populate the durable name, ESXi first sends an inquiry command to get a list of VPD pages supported by the device. Then ESXi issues commands to get data for all supported VPD pages. Due to an issue with the target array, the device might fail a command to get VPD page data for a page in the list with a `not supported` error. As a result, ESXi cannot populate the durable name property for the device.

This issue is resolved in this release. The fix ignores the error on command to get VPD page data, except pages `80h` and `83h` , if that data is not required for the generation of durable name.

PR 3184425: Port scan of a VXLAN Tunnel End Point (VTEP) on an ESXi host might result in an intermittent connectivity loss

Port scan of a VTEP on an ESXi host might result in an intermittent connectivity loss, but only under the following conditions:

1. Your environment has many VTEPs
2. All VTEPs are in the same IP subnet
3. The upstream switch is Cisco ACI

This issue is resolved in this release.

PR 3156627: Changing the mode of the virtual disk on a running virtual machine might cause the VM to fail

If you use the VMware Host Client to edit the disk mode of a running virtual machine, for example from Independent - Nonpersistent to Dependent or Independent - Persistent, the operation fails and might cause the VM to fail. In the `vmware.log` , you see errors such as:

```
msg.disk.notConfigured2] Failed to configure disk 'scsi0:4'. The virtual machine cannot be powered on with an unconfigured disk.
```

```
[msg.checkpoint.continuesync.error] An operation required the virtual machine to quiesce and the virtual machine was unable to continue running.
```

This issue is resolved in this release. The fix blocks changing the mode of an Independent - Nonpersistent disk on a running virtual machine by using the VMware Host Client. The vSphere Client already blocks such operations.

PR 3164477: In VMware Skyline Health Diagnostics, you see multiple warnings for vSAN memory pools

The free heap memory estimation logic for some vSAN memory pools might consider more memory heap than actual and trigger warnings for insufficient memory. As a result, you see `Memory pools (heap)` health warnings for many hosts under the **Physical disks** section in Skyline Health.

This issue is resolved in this release.

PR 3168950: ESXi hosts fail with a purple diagnostic screen while installing VMware NSX-T Data Center due to insufficient TCP/IP heap space

VMware NSX-T Data Center has multiple net stacks and the default TCP/IP heap space might not be sufficient for installation. As a result, ESXi hosts might fail with a purple diagnostic screen.

This issue is resolved in this release. The fix increases the default `TcpipHeapSize` setting to 8 MB from 0 MB and the maximum size to 128 MB from 32 MB. In the vSphere Client, you can change the `TcpipHeapSize` value by navigating to

Hosts and Clusters > Configure > System > Advanced System Settings > TcpipHeapSize. In vCenter systems with VMware NSX-T Data Center, set the value to 128 MB.

PR 3096974: Rare race condition in I/O filters might cause an ESXi host to fail with a purple diagnostics screen

ESXi hosts in which virtual machines use I/O filters might randomly fail with a purple diagnostics screen and an error such as `#DF Exception 8 IP 0x42002c54b19f SP 0x453a9e8c2000` due to a rare race condition.

This issue is resolved in this release.

PR 3112194: Spherelet might fail to start on an ESXi host due to the execInstalledOnly setting

The `execInstalledOnly` setting is a run time parameter which limits execution of binaries such as applications and vmkernel modules to improve security and guard against breaches and compromises. Some `execInstalledOnly` security checks might interfere with Spherelet, the ESXi UserWorld agent that acts as an extension to the Kubernetes Control Plane, and prevent it to start, even when all files are installed.

This issue is resolved in this release.

PR 3115870: VMware VIB installation might fail during concurrent vendor package installations

When you install update packages from several vendors, such as JetStream Software, Microsoft, and VMware, multiple clients call the same PatchManager APIs and might lead to a race condition. As a result, VMware installation packages (VIBs) might fail to install. In the logs, you see an error such as `vim.fault.PlatformConfigFault` , which is a catch-all fault indicating that some error has occurred regarding the configuration of the ESXi host. In the vSphere Client, you see a message such as `An error occurred during host configuration.`

This issue is resolved in this release. The fix is to return a `TaskInProgress` warning instead of `PlatformConfigFault` , so that you are aware of the actual issue and retry the installation.

PR 3164439: Certain applications might take too many ESXi file handles and cause performance aggravation

In very rare cases, applications such as NVIDIA virtual GPU (vGPU) might consume so many file handles that ESXi fails to process other services or VMs. As a result, you might see GPU on some nodes to disappear, or report zero GPU memory, or performance degradation.

This issue is resolved in this release. The fix reduces the number of file handles a vGPU VM can consume.

PR 3162963: If parallel volume expand and volume refresh operations on the same VMFS volume run on two ESXi hosts in the same cluster, the VMFS volume might go offline

While a VMFS volume expand operation is in progress on an ESXi host in a vCenter cluster, if on another host a user or vCenter initiates a refresh of the same VMFS volume capacity, such a volume might go offline. The issue occurs due to a possible mismatch in the device size, which is stamped on the disk in the volume metadata during a device rescan, and the device size value in the Pluggable Storage Architecture (PSA) layer on the host, which might not be updated if the device rescan is not complete.

This issue is resolved in this release. The fix improves the resiliency of the volume manager code to force a consecutive refresh of the device attributes and comparison of the device sizes again if vCenter reports a mismatch in the device size.

PR 3161690: CPU usage of ESXi hosts might intermittently increase in environments

Due to a rare race condition, when a VM power off command conflicts with a callback function, you might see increased CPU usage on ESXi hosts, for example, after an upgrade.

This issue is resolved in this release.

PR 3165374: ESXi hosts might become unresponsive and fail with a purple diagnostic screen during TCP TIME_WAIT

The TCP slow timer might starve TCP input processing while it covers the list of connections in `TIME_WAIT` closing expired connections due to contention on the global TCP pcbinfo lock. As a result, the VMkernel might fail with a purple

diagnostic screen and the error `Spin count exceeded - possible deadlock` while cleaning up `TCP TIME_WAIT` sockets. The backtrace points to tcpip functions such as `tcp_slowtimo()` or `tcp_twstart()`.

This issue is resolved in this release. The fix adds a new global lock to protect the list of connections in `TIME_WAIT` and to acquire the TCP pcbinfo lock only when closing an expired connection.

PR 3166818: If any of the mount points that use the same NFS server IP returns an error, VAAI-NAS might mark all mount points as not supported

When you use a VAAI-NAS vendor plug-in, multiple file systems on an ESXi host use the same NFS server IP to create a datastore. For certain NAS providers, if one of the mounts returns a `VIX_E_OBJECT_NOT_FOUND (25)` error during the `startSession` call, hardware acceleration for all file systems with the same NFS server IP might become unsupported. This issue occurs when an ESXi host mounts a directory on an NFS server, but that directory is not available at the time of the `startSession` call, because, for example, it has been moved from that NFS server.

This issue is resolved in this release. The fix makes sure that VAAI-NAS marks as not supported only mounts that report an error.

PR 3100030: An ESXi host fails with a purple diagnostic screen indicating VMFS heap corruption

A race condition in the host cache of a VMFS datastore might cause heap corruption and the ESXi host fails with a purple diagnostic screen and a message such as:

```
PF Exception 14 in world xxxxx:res3HelperQu IP 0xxxxxxe2 addr 0xXXXXXXXXX
```

This issue is resolved in this release.

PR 3121216: If the Internet Control Message Protocol (ICMPA) is not active, ESXi host reboot might take long after an upgrade

If ICMPA is not active on the NFS servers in your environment, after upgrading your system, ESXi hosts reboot might take an hour to complete, because restore operations for NFS datastores fail. NFS uses the `vmkping` utility to identify reachable IPs of the NFS servers before executing a mount operation and when ICMP is not active, mount operations fail.

This issue is resolved in this release. To remove dependency on the ICMP protocol to find reachable IPs, the fix adds socket APIs to ensure that IPs on a given NFS server are available.

PR 3098760: ESXi hosts randomly disconnect from the Active Directory domain or vCenter due to Likewise memory exhaustion

Memory leaks in Active Directory operations and related libraries, or when smart card authentication is enabled on an ESXi host, might lead to Likewise memory exhaustion.

This issue is partially resolved in this release. For more information, see VMware knowledge base article 78968.

PR 3118402: The NTP monitoring function returns intermittent time sync failure in the time services test report even when the ESXi host system clock is actually in sync

The time services monitoring infrastructure periodically queries the NTP daemon, ntpd, for time sync status on ESXi hosts. Intermittent query failures might occur due to timeouts in the socket call to read such status information. As a result, you might see time sync failure alerts in the NTP test reports.

This issue is resolved in this release. The fix makes sure that NTP monitoring queries do not fail.

PR 3159168: You see multiple "End path evaluation for device" messages in the vmkernel.log

A periodic device probe that evaluates the state of all the paths to a device might create multiple unnecessary `End path evaluation for device` messages in the `vmkernel.log` file on a release build.

This issue is resolved in this release. The fix restricts `End path evaluation for device` messages to only non-release builds, such as beta. You must enable the VERBOSE log level to see such logs.

PR 3101512: You see a warning for lost uplink redundancy even when the uplink is active

If you quickly remove the network cable from a physical NIC and reinsert it, the ESXi host agent, hostd, triggers an event to restore uplink redundancy, but in some cases, although the uplink restores in a second, you still see a misleading alarm for lost uplink redundancy.

This issue is resolved in this release.

PR 3161473: Operations with stateless ESXi hosts might not pick the expected remote disk for system cache, which causes remediation or compliance issues

Operations with stateless ESXi hosts, such as storage migration, might not pick the expected remote disk for system cache. For example, you want to keep the new boot LUN as LUN 0, but vSphere Auto Deploy picks LUN 1.

This issue is resolved in this release. The fix provides a consistent way to sort the remote disks and always pick the disk with the lowest LUN ID. To make sure you enable the fix, follow these steps:

1. On the Edit host profile page of the Auto Deploy wizard, select **Advanced Configuration Settings** > **SystemImage Cache Configuration** > **System Image Cache Configuration**
2. In the **System Image Cache Profile Settings** drop-down menu, select **Enable stateless caching on the host**.
3. Edit **Arguments** for first disk by replacing **remote** with **sortedremote** and/or **remoteesx** with **sortedremoteesx**.

PR 3187846: Setting the screen resolution of a powered off, encrypted virtual machine does not always work when manually editing the VMX file

If you manually specify the screen resolution of a powered off, encrypted virtual machine by editing the VMX file, the change might not take effect.

This issue is resolved in this release.

esx-update_7.0.3-0.105.22348816

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_bootbank_loadesx_7.0.3-0.105.22348816 • VMware_bootbank_esx-update_7.0.3-0.105.22348816
PRs Fixed	3245953, 3178109, 3211395, 3164477, 3119959, 3164462
CVE numbers	N/A

Updates the `loadesx` and `esx-update` VIBs.

Broadcom-lsi-msgpt3_17.00.12.00-2vmw.703.0.105.22348816

Affected Hardware	N/A
Affected Software	N/A

Affected VIBs	• VMW_bootbank_lsi-msgpt3_17.00.12.00-2vmw.703.0.105.22348816
PRs Fixed	3036883
CVE numbers	N/A

Updates the `ntg3` VIB to resolve the following issue:

PR 3036883: A SAS path might be lost during upgrade of lsi_msgpt3 drivers

Upgrading `lsi_msgpt3` drivers of version `17.00.12.00-1` and earlier might cause storage connections and VMs on ESXi host to become unresponsive due to a lost SAS path. In the VMkernel logs, you see error messages such as:

```
2022-06-19T05:25:51.949Z cpu26:2097947)WARNING: NMP: nmpDeviceAttemptFailover:640:
Retry world failover device "naa.6000d310045e2c000000000000000043" - issuing command

not select path for device "naa.6000d310045e2c000000000000000043".
```

```
2022-06-19T05:25:51.949Z cpu26:2097947)WARNING: NMP: nmpDeviceAttemptFailover:715: Retry
world failover device "naa.6000d310045e2c000000000000000043" - failed to issue command due
to Not found (APD), try again...
```

This issue is resolved in this release. If you already face the issue, rescan your storage after failing back on storage controller to recover the paths and storage connections.

Microchip-smartpqiv2-plugin_1.0.0-9vmw.703.0.105.22348816

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	No
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_bootbank_lsuv2-smartpqiv2-plugin_1.0.0-9vmw.703.0.105.22348816
PRs Fixed	3112692
CVE numbers	N/A

Updates the `lsuv2-smartpqiv2-plugin` VIB to resolve the following issue:

PR 3112692: The smartpqi driver cannot get the location of ThinkSystem PM1645a SAS SSD devices

In rare cases, the `smartpqi plugin in LSU service` might get a longer serial number string from the VPD page 0x80 than the actual serial number, and the device lookup in the cache fails. As a result, when you run the command `esxcli storage core device physical get -d <device_id>` to get a device location, you see an error such as `Unable to get location for device. Device is not found.`.

This issue is resolved in this release. The fix makes sure that the `smartpqi plugin in LSU service` always checks the correct serial number length and finds the device location.

VMware-NVMe-PCIe_1.2.3.16-3vmw.703.0.105.22348816

Patch Category	Bugfix

Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A

Affected VIBs	• VMW_bootbank_nvme-pcie_1.2.3.16-3vmw.703.0.105.22348816
PRs Fixed	3218578
CVE numbers	N/A

Updates the `nvme-pcie` VIB to resolve the following issue:

PR 3218578: You see wrong device descriptions of some Lenovo ThinkSystem boot RAID adapters

In a vSphere client interface, such as the vSphere Client, or when you run commands such as `lspci` and `esxcfg-scsidevs -a` from the ESXi shell, you might see the device names of some Lenovo-branded boot SATA/NVMe adapters as the generical names of the controller chips they use. For example, **Lenovo ThinkSystem M.2 with Mirroring Enablement Kit** is displayed as **88SE9230 PCIe SATA 6GB/s controller**.

This issue is resolved in this release.

VMware-ahci_2.0.11-2vmw.703.0.105.22348816

CVE numbers	N/A

The ESXi and esx-update bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.

Updates the `vsanhealth`, `crx`, `vdfs`, `esxio-combiner`, `native-misc-drivers`, `esx-base`, `esx-dvfilter-generic-fastpath`, `cpu-microcode`, `bmcal`, `esx-ui`, `gc`, `trx`, `vsan`, and `esx-xserver` VIBs to resolve the following issues:

ESXi 7.0 Update 3o provides the following security updates:

- The cURL library is updated to version 8.1.2.
- The ESXi userworld libxml2 library is updated to version 2.10.4.
- The SQLite library is updated to version 3.42.0.
- The OpenSSL package is updated to version 1.0.2zh.

The cpu-microcode VIB includes the following AMD microcode:

Updates the `tools-light` VIB.

The following VMware Tools ISO images are bundled with ESXi 7.0 Update 3o:

- **windows.iso**: VMware Tools 12.2.6 supports Windows 7 SP1 or Windows Server 2008 R2 SP1 and later.
- **linux.iso**: VMware Tools 10.3.25 ISO image for Linux OS with **glibc** 2.11 or later.

The following VMware Tools ISO images are available for download:

- VMware Tools 11.0.6:
  - **windows.iso**: for Windows Vista (SP2) and Windows Server 2008 Service Pack 2 (SP2).
- VMware Tools 10.0.12:
  - **winPreVista.iso**: for Windows 2000, Windows XP, and Windows 2003.
  - **linuxPreGLibc25.iso**: supports Linux guest operating systems earlier than Red Hat Enterprise Linux (RHEL) 5, SUSE Linux Enterprise Server (SLES) 11, Ubuntu 7.04, and other distributions with **glibc** version earlier than 2.5.
- **solaris.iso**: VMware Tools image 10.3.10 for Solaris.
- **darwin.iso**: Supports Mac OS X versions 10.11 and later. VMware Tools 12.1.0 was the last regular release for macOS. For more details, see VMware knowledge base article 88698.

Follow the procedures listed in the following documents to download VMware Tools for platforms not bundled with ESXi:

- Updating VMware Tools
- VMware Tools for hosts provisioned with Auto Deploy
- What Every vSphere Admin Must Know About VMware Tools
- Earlier versions of VMware Tools
- VMware Tools 12.2.6 Release Notes

ESXi-7.0U3o-22348816-standard

Profile Name	ESXi-7.0U3o-22348816-standard
Build	For build information, see Patches Contained in This Release.
Vendor	VMware, Inc.
Release Date	September 28, 2023
Acceptance Level	PartnerSupported
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_bootbank_gc_7.0.3-0.105.22348816 • VMware_bootbank_native-misc-drivers_7.0.3-0.105.22348816 • VMware_bootbank_vsanhealth_7.0.3-0.105.22348816 • VMware_bootbank_crx_7.0.3-0.105.22348816 • VMware_bootbank_esx-xserver_7.0.3-0.105.22348816 • VMware_bootbank_vdfs_7.0.3-0.105.22348816 • VMware_bootbank_cpu-microcode_7.0.3-0.105.22348816 • VMware_bootbank_esx-base_7.0.3-0.105.22348816 • VMware_bootbank_vsan_7.0.3-0.105.22348816 • VMware_bootbank_esxio-combiner_7.0.3-0.105.22348816 • VMware_bootbank_esx-ui_2.11.2-21988676 • VMware_bootbank_bmcal_7.0.3-0.105.22348816 • VMware_bootbank_esx-dvfilter-generic-fastpath_7.0.3-0.105.22348816 • Mware_bootbank_trx_7.0.3-0.105.22348816 • VMware_bootbank_loadesx_7.0.3-0.105.22348816 • VMware_bootbank_esx-update_7.0.3-0.105.22348816 • VMW_bootbank_lsi-msgpt3_17.00.12.00-2vmw.703.0.105.22348816 • VMware_bootbank_lsuv2-smartpqiv2-plugin_1.0.0-9vmw.703.0.105.22348816 • VMW_bootbank_nvme-pcie_1.2.3.16-3vmw.703.0.105.22348816 • VMW_bootbank_vmw-ahci_2.0.11-2vmw.703.0.105.22348816 • VMW_bootbank_iavmd_2.7.0.1157-3vmw.703.0.105.22348816 • VMware_locker_tools-light_12.2.6.22229486-22233486
PRs Fixed	3244098, 3216958, 3245763, 3242021, 3246132, 3253205, 3256804, 3239170, 3251981, 3215370, 3117615, 3248478, 3252676, 3235496, 3238026, 3236064, 3224739, 3224306, 3223755, 3216958, 3233958, 3185125, 3219264, 3221620, 3218835, 3185560, 3221099, 3211625, 3221860, 3228586, 3224604, 3223539, 3222601, 3217258, 3213041, 3216522, 3221591, 3216389, 3220004, 3217633, 3216548, 3216449, 3156666, 3181574, 3180746, 3155476, 3211807, 3154090, 3184008, 3183519, 3183519, 3209853, 3100552, 3187846, 3113263, 3176350, 3185827, 3095511, 3184425, 3186351, 3186367, 3154090, 3158524, 3181601, 3180391, 3180283, 3184608, 3181774, 3155476, 3163361, 3182978, 3184368, 3160456, 3164575, 3181901, 3184871, 3166818, 3157195, 3164355, 3163271, 3112194, 3161690, 3261925, 3178589, 3178721, 3162963, 3168950, 3159168, 3158491, 3158866, 3096769, 3165374, 3122037, 3098760, 3164439, 3161473,

Related CVE numbers	N/A

This patch updates the following issues:

PR 3187846: Setting the screen resolution of a powered off, encrypted virtual machine does not always work when manually editing the VMX file

If you manually specify the screen resolution of a powered off, encrypted virtual machine by editing the VMX file, the change might not take effect.

This issue is resolved in this release.

PR 3253205: Static IPv6 gateway disappears in 18 hours

If you configure a static IPv6 gateway address in your vSphere environment, such gateways might no longer exist in up to 18 hours due to a timeout.

This issue is resolved in this release. The fix removes the existing timeout for static gateways.

PR 3272532: You see speed as Half Duplex after changing the speed from Auto to Full on a VMNIC

In some cases, length checks during the parsing of duplex TLVs in an environment with active Cisco Discovery Protocol (CDP) might fail. As a result, when you change the speed from **Auto** to **Full** on a physical NIC on peer devices you do not see the real duplex value in the TLV under the neighbor information, but the default Half Duplex value.

This issue is resolved in this release.

PR 3251981: An NFSv4.1 file might appear to be empty even though it contains data

When you open an existing NFSv4.1 file with write only access, if for some reason the NFS client opens again the same file with read only access, read operations from the client might return no data although the file is not empty.

This issue is resolved in this release.

PR 3116601: When you override the default gateway for the vSAN VMkernel adapter on an ESXi host, the vSphere HA agent on the host displays as inaccessible

In some cases, when you override the default gateway for the vSAN VMkernel adapter on an ESXi host, the Fault Domain Manager (FDM), which is the agent that vSphere HA deploys on ESX hosts, might stop receiving Internet Control Message Protocol (ICMP) pings. As a result, FDM might issue false cluster alarms that the vSphere HA agent on the host cannot reach some management network addresses of other hosts.

This issue is resolved in this release.

PR 3251801: vSphere vMotion operation from a 6.7.x ESXi host with an Intel Ice Lake CPU fails with msg.checkpoint.cpucheck.fail

vSphere vMotion operations by using either the vSphere Client or VMware Hybrid Cloud Extension (HCX) from an Intel Ice Lake CPU host running ESXi 6.7.x fails with an error such as `msg.checkpoint.cpucheck.fail` . In the vSphere Client, you see a message that cpuid.PSFD is not supported on the target host. In HCX, you see a report such as `A general system error occurred: vMotion failed:` .

This issue is resolved in this release.

PR 3036883: A SAS path might be lost during upgrade of lsi_msgpt3 drivers

Upgrading `lsi_msgpt3` drivers of version `17.00.12.00-1` and earlier might cause storage connections and VMs on ESXi host to become unresponsive due to a lost SAS path. In the VMkernel logs, you see error messages such as:

```
2022-06-19T05:25:51.949Z cpu26:2097947)WARNING: NMP: nmpDeviceAttemptFailover:640:
Retry world failover device "naa.6000d310045e2c000000000000000043" - issuing command
0x459acc1f5dc0
```

```
2022-06-19T05:25:51.949Z cpu26:2097947)WARNING: vmw_psp_rr: psp_rrSelectPath:2177: Could
not select path for device "naa.6000d310045e2c000000000000000043".
```

```
2022-06-19T05:25:51.949Z cpu26:2097947)WARNING: NMP: nmpDeviceAttemptFailover:715: Retry
world failover device "naa.6000d310045e2c000000000000000043" - failed to issue command due
to Not found (APD), try again...
```

This issue is resolved in this release. If you already face the issue, rescan your storage after failing back on storage controller to recover the paths and storage connections.

PR 3224739: You see alarms for dropped syslog messages

If the network throughput of your vSphere system does not align with the speed at which log messages are generated, some of the log messages sent to the remote syslog server might drop. As a result, in the vSphere Client you see host errors of type `Triggered Alarm` and in the logs, you see warnings such as `ALERT: vmsyslog logger xxxx:514 lost yyyy log messages.`

This issue is resolved in this release. The fix improves the network logging performance of the logging service to reduce the number of such lost log messages.

PR 3247027: If any failure occurs during a vSphere vMotion migration of NVIDIA virtual GPU (vGPU) VM, the destination ESXi host might fail with a purple diagnostic screen

In very rare cases, if any type of failure occurs during a vSphere vMotion migration of a vGPU VM, the vMotion operation is marked as a failure while a specific internal operation is in progress. As a result, the destination ESXi host might fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3095511: The SFCB service intermittently fails and generates "sfcb-vmware_bas-zdump" files on multiple ESXi hosts

In very rare cases, when the SFCB service tries to access an uninitialized variable, the service might fail with dump file such as `sfcb-vmware_bas-zdump.000`. The issue occurs because accessing an uninitialized variable can cause the SFCB process to keep requesting memory until it exceeds the heap allocation.

This issue is resolved in this release.

PR 3218578: You see wrong device descriptions of some Lenovo ThinkSystem boot RAID adapters

In a vSphere client interface, such as the vSphere Client, or when you run commands such as `lspci` and `esxcfg-scsidevs -a` from the ESXi shell, you might see the device names of some Lenovo-branded boot SATA/NVMe adapters as the generical names of the controller chips they use. For example, **Lenovo ThinkSystem M.2 with Mirroring Enablement Kit** is displayed as **88SE9230 PCIe SATA 6GB/s controller**.

This issue is resolved in this release.

PR 3256804: File server loses connectivity after failover when running vSAN File Service on NSX overlay network

If vSAN File Service is running on an NSX overlay network, the file server might lose connectivity after it fails over from one agent VM to another agent VM. The file server can failover when reconfiguring file service domain from such without Active Directory(AD) to such with AD, or if vSAN detects unhealthy behavior in the file server, file share, or AD server. If file server connectivity is lost after a failover, File Service clients cannot access the file share. The following health warning might be reported:

`One or more DNS servers is not reachable.`

This issue is resolved in this release.

PR 3217633: vSAN management service on the orchestration host malfunctions during vCenter restart

This issue can occur on vSAN clusters where vCenter is deployed. If multiple cluster shutdown operations are performed, the `/etc/vmware/vsan/vsanperf.conf` file on the orchestration host can contain two versions of the following management VM: `vc_vm_moIdvc_vm_moid` . These configuration options conflict with each other and can cause the vSAN management service to malfunction.

This issue is resolved in this release.

PR 3224306: When you change the ESXi syslog setting syslog.global.logDir, if syslog.global.logDirUnique is active, you might see 2 levels of <hostname> subdir under the logdir path

After upgrading an ESXi host to 7.0 Update 3c and later, if you change the syslog setting `syslog.global.logDir` and the `syslog.global.logDirUnique` setting is active, you might see 2 levels of `<hostname>` subdirs under the `logdir` path on the host. The `syslog.global.logDirUnique` setting is useful if the same NFS directory is configured as the `Syslog.global.LogDir` by multiple ESXi hosts, as it creates a subdirectory with the name of the ESXi host under `logdir` .

This issue is resolved in this release.

PR 3223755: ESXi syslog daemon fails to resume transmitting logs to the configured SSL remote syslog server once a drop in the network connectivity restores

If a remote SSL syslog server temporarily loses connectivity, the ESXi syslog daemon might fail to resume transmitting logs after connectivity restores and you must restart the service to re-activate transmissions. The issue occurs due to some unhandled exceptions while the ESXi syslog daemon tries to restore connection to the SSL remote syslog server.

This issue is resolved in this release. The fix adds a generic catch for all unhandled exceptions.

PR 3185536: vSAN cluster remediation error after vCenter upgrade to 7.0 Update 3

When you upgrade vCenter from version 6.5.x to 7.0 Update 3, and reconfigure the vSAN cluster, a vSAN cluster remediation is triggered, but in some cases fails.

This issue is resolved in this release.

PR 3110401: The Explicit Congestion Notification (ECN) setting is not persistent on ESXi host reboot

ECN, specified in RFC 3168, allows a TCP sender to reduce the transmission rate to avoid packet drops and is activated by default. However, if you change the default setting, or manually deactivate ECN, such changes to the ESXi configuration might not persist after a reboot of the host.

This issue is resolved in this release.

PR 3153395: Upon refresh, some dynamic firewalls rules might not persist and lead to vSAN iSCSI Target service failure

If you frequently run the command `esxcli network firewall refresh` , a race condition might cause some dynamic firewalls rules to be removed upon refresh or load. As a result, some services such as the vSAN iSCSI Target daemon, which provides vSAN storage with iSCSI protocol, might fail.

This issue is resolved in this release.

PR 3096769: You see high latency for VM I/O operations in a vSAN cluster with Unmap activated

This issue affects vSAN clusters with Unmap activated. A problem in Unmap handling in LSOM creates log congestion. The log congestion can cause high VM I/O latency.

This issue is resolved in this release.

PR 3163361: The Audit Record Storage Capacity parameter does not persist across ESXi host reboots

After an ESXi host reboot, you see the **Audit Record Storage Capacity** parameter restored to the default value of 4 MiB, regardless of any previous changes.

This issue is resolved in this release.

PR 3162496: If the Internet Control Message Protocol (ICMPA) is not active, ESXi host reboot might take long after upgrading to vSphere 8.0 and later

If ICMPA is not active on the NFS servers in your environment, after upgrading your system to vSphere 8.0 and later, ESXi hosts reboot might take an hour to complete, because restore operations for NFS datastores fail. NFS uses the `vmkping` utility to identify reachable IPs of the NFS servers before executing a mount operation and when ICMP is not active, mount operations fail.

This issue is resolved in this release. To remove dependency on the ICMP protocol to find reachable IPs, the fix adds socket APIs to ensure that IPs on a given NFS server are available.

PR 3220004: VBS-enabled Windows VMs might fail with a blue diagnostic screen when an ESXi host is under memory pressure

Windows VMs with virtualization-based security (VBS) enabled might intermittently fail with a blue diagnostic screen during memory-heavy operations such as deleting snapshots or consolidating disks. The BSOD has the following signature:

```
DRIVER_VERIFIER_DMA_VIOLATION (e6)
An illegal DMA operation was attempted by a driver being verified.
```

Arguments:

```
Arg1: 0000000000000026, IOMMU detected DMA violation.
Arg2: 0000000000000000, Device Object of faulting device.
Arg3: xxxxxxxxxxxxxxxx, Faulting information (usually faulting physical address).
Arg4: 0000000000000008, Fault type (hardware specific).
```

This issue is resolved in this release.

PR 3162905: ESXi hosts might intermittently disconnect from vCenter in case of memory outage

In rare cases, if vCenter fails to allocate or transfer active bitmaps due to an alert for insufficient memory for any reason, the hostd service might repeatedly fail and you cannot reconnect the host to the vCenter.

This issue is resolved in this release. The fix makes sure that in such cases you see an error rather than the hostd service failure.

PR 3108979: Staging ESXi patches and ESXi upgrade tasks might become indefinitely unresponsive due to a log buffer limit

If a large string or log exceed the python log buffer limit of 16K, the logger becomes unresponsive. As a result, when you stage ESXi patches on a host by using the vSphere Client, the process responsible for completing the staging task on ESXi might become indefinitely unresponsive. The task times out and reports an error. The issue occurs also when you remediate ESXi hosts by using a patch baseline.

This issue is resolved in this release. The fix breaks the large input string into smaller chunks for logging.

PR 3219264: vSAN precheck for maintenance mode or disk decommission doesn't list objects that might lose accessibility

This issue affects objects with resyncing components, and some components reside on a device to be removed or placed into maintenance mode. When you run a precheck with the **No-Action** option, the precheck does not evaluate the object correctly to report it in the `inaccessibleObjects` list.

This issue is resolved in this release. Precheck includes all affected objects in the `inaccessibleObjects` list.

PR 3186545: Vulnerability scans might report the HTTP TRACE method on vCenter ports 9084 and 9087 as vulnerable

Some third-party tools for vulnerability scans might report the HTTP TRACE method on vCenter ports 9084 and 9087 as vulnerable.

This issue is resolved in this release.

PR 3221591: ESXi NVMe/TCP initiator fails to recover paths after target failure recovery

When a NVMe/TCP target recovers from a failure, ESXi cannot recover the path.

This issue is resolved in this release.

PR 3186351: You see an override flag of NIC teaming, security, or traffic shaping policy on a portgroup unexpectedly enabled post an ESXi host reboot

In some cases, a networking configuration might not persist in the ESXi ConfigStore and you see an override flag of NIC teaming, security, or traffic shaping policy on a portgroup unexpectedly enabled post an ESXi host reboot.

This issue is resolved in this release.

PR 3162790: The sfcb daemon might fail with a core dump while installing a third-party CIM provider

The sfcb daemon might try to access already freed memory when registering a CIM provider and fail with a core dump while installing a third-party CIM provider, such as Dell OpenManage Server Administrator for example.

This issue is resolved in this release.

PR 3157195: ESX hosts might fail with a purple diagnostic screen and an error NMI IPI: Panic requested by another PCPU

The resource pool cache is a VMFS specific volume level cache that stores the resource clusters corresponding to the VMFS volume. While searching for priority clusters, the cache flusher workflow iterates through a large list of cached resource clusters, which can cause lockup of the physical CPUs. As a result, ESX hosts might fail with a purple diagnostic screen. In the `logDump` file, you see an error such as:

```
^[[7m2022-10-22T07:56:47.322Z cpu13:2101160)WARNING: Heartbeat: 827: PCPU 0 didn't have a heartbeat for 7 seconds, timeout is 14, 1 IPIs sent; *may* be locked up.^[[0m^
[[31;1m2022-10-22T07:56:47.322Z cpu0:2110633)ALERT: NMI: 710: NMI IPI: RIPOFF(base):RBP:CS
```

This issue is resolved in this release.

PR 3230493: If a delta sync runs while the target vSphere Replication server is not active, Windows virtual machines might become unresponsive

If the target Sphere Replication server is not active during a delta sync, the synchronization process cannot complete and Windows virtual machines become unresponsive.

This issue is resolved in this release. The fix makes sure that no delta sync jobs start when a Sphere Replication server is not active.

PR 3122037: ESXi ConfigStore database fills up and writes fail

Stale data related to block devices might not be deleted in time from the ESXi ConfigStore database and cause an out of space condition. As a result, write operations to ConfigStore start to fail. In the backtrace, you see logs such as:

`2022-12-19T03:51:42.733Z cpu53:26745174)WARNING: VisorFSRam: 203: Cannot extend visorfs file /etc/vmware/configstore/current-store-1-journal because its ramdisk (configstore) is full .`

This issue is resolved in this release.

PR 3246132: You see a system clock drift on an ESXi host after synchronization with the NTP server fails

If connectivity between the NTP server and an ESXi host is delayed for some reason, the system clock on the ESXi host might experience a drift. When you run the `vsish` command `vsish -e get /system/ntpclock/clockData` , you might see a large negative value for the `adjtime` field. For example:

```
NTP clock data {
...  adjtime() (usec):-309237290312 <<<<<<
...
}
```

This issue is resolved in this release.

PR 3185560: vSphere vMotion operations for virtual machines with swap files on a vSphere Virtual Volumes datastore intermittently fail after a hot extend of the VM disk

vSphere vMotion operations for virtual machines with swap files on a vSphere Virtual Volumes datastore might fail under the following circumstances:

A VM that runs on ESXi host A is migrated to ESXi host B, then the VM disk is hot extended, and the VM is migrated back to ESXi host A. The issue occurs due to stale statistics about the swap virtual volume.

This issue is resolved in this release.

PR 3236207: You cannot unmount an NFS v3 datastore from a vCenter system because the datastore displays as inaccessible

While unmounting an NFSv3 datastore from a vCenter system by using either the vSphere Client or ESXCLI, you might see the datastore either as inaccessible, or get an `Unable to Refresh` error. The issue occurs when a hostd cache refresh happens before NFS deletes the mount details from ConfigStore, which creates a rare race condition.

This issue is resolved in this release.

PR 3236064: Compliance or remediation scans by using vSphere Lifecycle Manager might take long on ESXi hosts with a large number of datastores

Compliance or remediation scans by using vSphere Lifecycle Manager include an upgrade precheck that lists all volumes attached to an ESXi host, their free space, versions, and other details. If a host has many datastores attached, each with a large capacity, the precheck can take long. The time is multiplied by the number of baselines attached to the cluster or host.

This issue is resolved in this release. If you already face the issue, disconnect the attached datastores while performing the remediation or compliance scans and reattach them after the operations complete.

PR 3245763: During a vSphere vMotion operation, destination ESXi hosts with a Distributed Firewall (DFW) enabled might fail with a purple diagnostic screen

If the destination host in a vSphere vMotion operation has a DFW enabled, a rare race condition might cause the host to fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3158866: Virtual machines might become unresponsive during VMFS volume expansion due to a Logical Volume Manager (LVM) check

If a VMFS volume expansion operation happens during a LVM probe to update volume attributes, such as the size of the VMFS partition backing of the VMFS volume, the current size of the VMFS volume might not match the LVM metadata on the disk. As a result, LVM marks such a volume offline and virtual machines on that volume become unresponsive.

This issue is resolved in this release. The fix improves Input Output Control (IOCTL) to speed up the update of device attributes and avoid such cases.

PR 3152717: vSphere Auto Deploy workflows might fail after an upgrade to vCenter Server 7.0 Update 3j or later

Due to a networking issue in reverse proxy configuration environments, vSphere Auto Deploy workflows might fail after an upgrade to vCenter Server 7.0 Update 3j or later. In the ESXi management console and in the `/var/log/vmware/rbd/rbd-cgi.log file` you see an HTTP client error.

This issue is resolved in this release. The fix makes sure Auto Deploy workflows run successfully in reverse proxy configuration environments.

PR 3185125: Virtual SLIT table not populated for the guest OS when using sched.nodeX.affinity

When you specify virtual NUMA node affinity, the vSLIT table might not be populated and you see the following error in `vmware.log : vSLIT: NumaGetLatencyInfo failed with status: 195887107.`

This happens when setting node affinity as follows:

```
numa.slit.enable = "TRUE"

sched.node0.affinity = 0

sched.node1.affinity = 1

...sched.nodeN.affinity = N
```

This issue is resolved in this release. If you already face the issue, specify VCPU affinity to physical CPUs on the associated NUMA nodes, instead of node affinity.

For example:

```
numa.slit.enable = "TRUE"

sched.vcpu0.affinity = "0-7"

sched.vcpu1.affinity = "0-7"

...sched.vcpuN.affinity = "Y-Z"
```

PR 3181774: You do not see an error when you attach a CBT enabled FCD to a VM with CBT disabled

Attaching a First Class Disk (FCD) with Changed Block Tracking (CBT) to a VM with CBT disabled does not throw a detailed error, but the operation cannot take effect. In the backtrace, you might see an error message such as `InvalidState` , which is generic and does not provide details on the issue.

This issue is resolved in this release. The fix adds the error message `Cannot attach a CBT enabled fcd: {path} to CBT disabled VM.` to the logs of the hostd service and adds a status message for the task in the vSphere Client.

PR 3185827: You see trap files in a SNMP directory under /var/spool even though SNMP is not enabled

After the hostd service starts, for example after an ESXi host reboot, it might create a SNMP directory under `/var/spool` and you see many `.trp` files to pile in this directory.

This issue is resolved in this release. The fix makes sure that the directory `/var/spool/snmp` exists only when SNMP is enabled.

PR 3082867: An ESXi host might fail with a purple diagnostic screen after a replicated virtual machine migrates to the host

In some environments, when a replicated virtual machine migrates to a certain ESXi host, during a full sync, some `SCSI WRITE` commands might target address ranges past the end of the transfer map. As a result, the ESXi host might fail with a purple diagnostic screen and a backtrace such as:

```
#0 DLM_free (msp=0x43238f2c9cc0, mem=mem@entry=0x43238f6db860, allowTrim=allowTrim@entry=1
'\001') at bora/vmkernel/main/dlmalloc.c:4924

#1 0x000041802a151e01 in Heap_Free (heap=0x43238f2c9000, mem=<optimized out>) at bora/
vmkernel/main/heap.c:4217

#2 0x000041802a3b0fa1 in BitVector_Free (heap=<optimized out>, bv=<optimized out>) at
bora/vmkernel/util/bitvector.c:94

#3 0x000041802b9f4f3f in HbrBitmapFree (bitmap=<optimized out>) at bora/modules/vmkernel/
hbr_filter/hbr_bitmap.c:91
```

This issue is resolved in this release.

PR 3162499: During service insertion for NSX-managed workload VMs, some VMS might become intermittently unresponsive, and the virtual device might reset

During service insertion for NSX-managed workload VMs, a packet list might be reinjected from the input chain of one switchport to another switchport. In such cases, the source switchport does not correspond to the actual `portID` of the input chain and the virtual device does not get completion status for the transmitted frame. As a result, when you run a service insertion task, some VMs might become intermittently unresponsive due to network connectivity issues.

This issue is resolved in this release.

PR 3219441: You cannot send keys to a guest OS by using the browser console in the ESXi Host Client

In the ESXi Host Client, when you open the browser console of a virtual machine and select **Guest OS > Send keys**, when you select a key input, for example **Ctrl-Alt-Delete**, the selection is not sent to the guest OS.

This issue is resolved in this release.

PR 3209853: Windows VMs might fail with a blue diagnostic screen with 0x5c signature due to platform delays

Windows VMs might fail with a blue diagnostic screen with the following signature due to a combination of factors involving the Windows timer code and platform delays, such as storage or network delays:

`HAL_INITIALIZATION_FAILED (0x5c)` (This indicates that the HAL initialization failed.)

Arguments:

```
Arg1: 0000000000000115, HAL_TIMER_INITIALIZATION_FAILURE

Arg2: fffff7ea800153e0, Timer address

Arg3: 00000000000014da, Delta in QPC units (delta to program the timer with)

Arg4: ffffffffc0000001, invalid status code (STATUS_UNSUCCESSFUL)
```

Checks done by HPET timers in Windows might fail due to such platform delays and cause the issue.

This issue is resolved in this release.

PR 3178109: vSphere Lifecycle Manager compliance check fails with "An unknown error occurred while performing the operation"

The base ESXi image contains driver components that can be overridden by higher version async driver components packaged by an OEM add-on. If such a component is manually removed on a host, the compliance check of the vSphere Lifecycle Manager might fail unexpectedly. In the vSphere Client, you see errors such as `Host status is unknown` and `An unknown error occurred while performing the operation.`

This issue is resolved in this release.

PR 3180634: Performance of certain nested virtual machines on AMD CPUs might degrade

Nested virtual machines on AMD CPUs with operational systems such as Windows with virtualization-based security (VBS) might experience performance degradation, timeouts, or unresponsiveness due to an issue with the virtualization of AMD's Rapid Virtualization Indexing (RVI), also known as Nested Page Tables (NPT).

This issue is resolved in this release.

PR 3223539: Some vmnics might not be visible after an ESXi host reboot due to a faulty NVMe device

If an NVMe device fails during the attach phase, the NVMe driver disables the NVMe controller and resets the hardware queue resources. When you try to re-attach the device, a mismatch between the hardware and driver queue pointers might cause an IOMMU fault on the NVMe device, which leads to memory corruption and failure of the vmkdevmgr service. As a result, you do not see some vmnics in your network.

This issue is resolved in this release.

PR 3218835: When you disable or suspend vSphere Fault Tolerance, virtual machines might become unresponsive for about 10 seconds

When you disable or suspend vSphere FT, some virtual machines might take about 10 seconds to release vSphere FT resources. As a result, such VMs become temporarily unresponsive to network requests or console operations.

This issue is resolved in this release.

PR 3181901: ESXi host becomes unresponsive and you cannot put the host in Maintenance Mode or migrate VMs from that host

Asynchronous reads of metadata on a VMFS volume attached to an ESXi host might cause a race condition with other threads on the host and make the host unresponsive. As a result, you cannot put the host in Maintenance Mode or migrate VMs from that host.

This issue is resolved in this release.

PR 3156666: Packets with length less than 60 bytes might drop

An ESXi host might add invalid bytes, other than zero, to packets with less than 60 bytes. As a result, packets with such invalid bytes drop.

This issue is resolved in this release.

PR 3180283: When you migrate a VM with recently hot-added memory, an ESXi host might repeatedly fail with a purple diagnostic screen

Due to a race condition while the memory hotplug module recomputes the NUMA memory layout of a VM on a destination host after migration, an ESXi host might repeatedly fail with a purple diagnostic screen. In the backtrace, you see errors such as:

```
0x452900262cf0:[0x4200138fee8b]PanicvPanicInt@vmkernel#nover+0x327 stack: 0x452900262dc8,

```

This issue is resolved in this release.

PR 3100552: ESXi booting times out after five minutes and the host automatically reboots

During initial ESXi booting, when you see the **Loading VMware ESXi** progress bar, if the bootloader takes more than a total of five minutes to load all the boot modules before moving on to the next phase of booting, the host firmware times out the boot process and resets the system.

This issue is resolved in this release. With ESXi 7.0 Update 3o, the ESXi bootloader resets the five-minute timeout after each boot module loads.

PR 3184368: The durable name of a SCSI LUN might not be set

The durable name property for a SCSI-3 compliant device comes from pages `80h` and `83h` of the Vital Product Data (VPD) as defined by the T10 and SMI standards. To populate the durable name, ESXi first sends an inquiry command to get a list of VPD pages supported by the device. Then ESXi issues commands to get data for all supported VPD pages. Due to an issue with the target array, the device might fail a command to get VPD page data for a page in the list with a `not supported` error. As a result, ESXi cannot populate the durable name property for the device.

This issue is resolved in this release. The fix ignores the error on command to get VPD page data, except pages `80h` and `83h` , if that data is not required for the generation of durable name.

PR 3184425: Port scan of a VXLAN Tunnel End Point (VTEP) on an ESXi host might result in an intermittent connectivity loss

Port scan of a VTEP on an ESXi host might result in an intermittent connectivity loss, but only under the following conditions:

1. Your environment has many VTEPs
2. All VTEPs are in the same IP subnet
3. The upstream switch is Cisco ACI

This issue is resolved in this release.

PR 3156627: Changing the mode of the virtual disk on a running virtual machine might cause the VM to fail

If you use the VMware Host Client to edit the disk mode of a running virtual machine, for example from Independent - Nonpersistent to Dependent or Independent - Persistent, the operation fails and might cause the VM to fail. In the `vmware.log` , you see errors such as:

```
msg.disk.notConfigured2] Failed to configure disk 'scsi0:4'. The virtual machine cannot be
powered on with an unconfigured disk.
```

```
[msg.checkpoint.continuesync.error] An operation required the virtual machine to quiesce
and the virtual machine was unable to continue running.
```

This issue is resolved in this release. The fix blocks changing the mode of an Independent - Nonpersistent disk on a running virtual machine by using the VMware Host Client. The vSphere Client already blocks such operations.

PR 3164477: In VMware Skyline Health Diagnostics, you see multiple warnings for vSAN memory pools

The free heap memory estimation logic for some vSAN memory pools might consider more memory heap than actual and trigger warnings for insufficient memory. As a result, you see `Memory pools (heap)` health warnings for many hosts under the **Physical disks** section in Skyline Health.

This issue is resolved in this release.

PR 3168950: ESXi hosts fail with a purple diagnostic screen while installing VMware NSX-T Data Center due to insufficient TCP/IP heap space

VMware NSX-T Data Center has multiple net stacks and the default TCP/IP heap space might not be sufficient for installation. As a result, ESXi hosts might fail with a purple diagnostic screen.

This issue is resolved in this release. The fix increases the default `TcpipHeapSize` setting to 8 MB from 0 MB and the maximum size to 128 MB from 32 MB. In the vSphere Client, you can change the `TcpipHeapSize` value by navigating to **Hosts and Clusters > Configure > System > Advanced System Settings > TcpipHeadSize**. In vCenter systems with VMware NSX-T Data Center, set the value to 128 MB.

PR 3096974: Rare race condition in I/O filters might cause an ESXi host to fail with a purple diagnostics screen

ESXi hosts in which virtual machines use I/O filters might randomly fail with a purple diagnostics screen and an error such as `#DF Exception 8 IP 0x42002c54b19f SP 0x453a9e8c2000` due to a rare race condition.

This issue is resolved in this release.

PR 3112194: Spherelet might fail to start on an ESXi host due to the execInstalledOnly setting

The `execInstalledOnly` setting is a run time parameter which limits execution of binaries such as applications and vmkernel modules to improve security and guard against breaches and compromises. Some `execInstalledOnly` security checks might interfere with Spherelet, the ESXi UserWorld agent that acts as an extension to the Kubernetes Control Plane, and prevent it to start, even when all files are installed.

This issue is resolved in this release.

PR 3115870: VMware VIB installation might fail during concurrent vendor package installations

When you install update packages from several vendors, such as JetStream Software, Microsoft, and VMware, multiple clients call the same PatchManager APIs and might lead to a race condition. As a result, VMware installation packages (VIBs) might fail to install. In the logs, you see an error such as `vim.fault.PlatformConfigFault` , which is a catch-all fault indicating that some error has occurred regarding the configuration of the ESXi host. In the vSphere Client, you see a message such as `An error occurred during host configuration.`

This issue is resolved in this release. The fix is to return a `TaskInProgress` warning instead of `PlatformConfigFault` , so that you are aware of the actual issue and retry the installation.

PR 3164439: Certain applications might take too many ESXi file handles and cause performance aggravation

In very rare cases, applications such as NVIDIA virtual GPU (vGPU) might consume so many file handles that ESXi fails to process other services or VMs. As a result, you might see GPU on some nodes to disappear, or report zero GPU memory, or performance degradation.

This issue is resolved in this release. The fix reduces the number of file handles a vGPU VM can consume.

PR 3162963: If parallel volume expand and volume refresh operations on the same VMFS volume run on two ESXi hosts in the same cluster, the VMFS volume might go offline

While a VMFS volume expand operation is in progress on an ESXi host in a vCenter cluster, if on another host a user or vCenter initiates a refresh of the same VMFS volume capacity, such a volume might go offline. The issue occurs due to a possible mismatch in the device size, which is stamped on the disk in the volume metadata during a device rescan, and the device size value in the Pluggable Storage Architecture (PSA) layer on the host, which might not be updated if the device rescan is not complete.

This issue is resolved in this release. The fix improves the resiliency of the volume manager code to force a consecutive refresh of the device attributes and comparison of the device sizes again if vCenter reports a mismatch in the device size.

PR 3161690: CPU usage of ESXi hosts might intermittently increase in environments that use a Vigor router

Due to a rare race condition, when a VM power off command conflicts with a callback function by a Vigor router, you might see increased CPU usage on ESXi hosts, for example, after an upgrade.

This issue is resolved in this release.

PR 3165374: ESXi hosts might become unresponsive and fail with a purple diagnostic screen during TCP TIME_WAIT

The TCP slow timer might starve TCP input processing while it covers the list of connections in `TIME_WAIT` closing expired connections due to contention on the global TCP pcbinfo lock. As a result, the VMkernel might fail with a purple diagnostic screen and the error `Spin count exceeded - possible deadlock` while cleaning up `TCP TIME_WAIT` sockets. The backtrace points to tcpip functions such as `tcp_slowtimo()` or `tcp_twstart()` .

This issue is resolved in this release. The fix adds a new global lock to protect the list of connections in `TIME_WAIT` and to acquire the TCP pcbinfo lock only when closing an expired connection.

PR 3166818: If any of the mount points that use the same NFS server IP returns an error, VAAI-NAS might mark all mount points as not supported

When you use a VAAI-NAS vendor plug-in, multiple file systems on an ESXi host use the same NFS server IP to create a datastore. For certain NAS providers, if one of the mounts returns a `VIX_E_OBJECT_NOT_FOUND (25)` error during the `startSession` call, hardware acceleration for all file systems with the same NFS server IP might become unsupported. This issue occurs when an ESXi host mounts a directory on an NFS server, but that directory is not available at the time of the `startSession` call, because, for example, it has been moved from that NFS server.

This issue is resolved in this release. The fix makes sure that VAAI-NAS marks as not supported only mounts that report an error.

PR 3112692: The smartpqi driver cannot get the location of ThinkSystem PM1645a SAS SSD devices

In rare cases, the `smartpqi plugin in LSU service` might get a longer serial number string from the VPD page 0x80 than the actual serial number, and the device lookup in the cache fails. As a result, when you run the command `esxcli storage core device physical get -d <device_id>` to get a device location, you see an error such as `Unable to get location for device. Device is not found.` .

This issue is resolved in this release. The fix makes sure that the `smartpqi plugin in LSU service` always checks the correct serial number length and finds the device location.

PR 3100030: An ESXi host fails with a purple diagnostic screen indicating VMFS heap corruption

A race condition in the host cache of a VMFS datastore might cause heap corruption and the ESXi host fails with a purple diagnostic screen and a message such as:

```
PF Exception 14 in world xxxxx:res3HelperQu IP 0xxxxxxe2 addr 0xXXXXXXXXX
```

This issue is resolved in this release.

PR 3121216: If the Internet Control Message Protocol (ICMPA) is not active, ESXi host reboot might take long after an upgrade

If ICMPA is not active on the NFS servers in your environment, after upgrading your system, ESXi hosts reboot might take an hour to complete, because restore operations for NFS datastores fail. NFS uses the `vmkping` utility to identify reachable IPs of the NFS servers before executing a mount operation and when ICMP is not active, mount operations fail.

This issue is resolved in this release. To remove dependency on the ICMP protocol to find reachable IPs, the fix adds socket APIs to ensure that IPs on a given NFS server are available.

PR 3098760: ESXi hosts randomly disconnect from the Active Directory domain or vCenter due to Likewise memory exhaustion

Memory leaks in Active Directory operations and related libraries, or when smart card authentication is enabled on an ESXi host, might lead to Likewise memory exhaustion.

This issue is partially resolved in this release. For more information, see VMware knowledge base article 78968.

PR 3118402: The NTP monitoring function returns intermittent time sync failure in the time services test report even when the ESXi host system clock is actually in sync

The time services monitoring infrastructure periodically queries the NTP daemon, ntpd, for time sync status on ESXi hosts. Intermittent query failures might occur due to timeouts in the socket call to read such status information. As a result, you might see time sync failure alerts in the NTP test reports.

This issue is resolved in this release. The fix makes sure that NTP monitoring queries do not fail.

PR 3159168: You see multiple "End path evaluation for device" messages in the vmkernel.log

A periodic device probe that evaluates the state of all the paths to a device might create multiple unnecessary `End path evaluation for device` messages in the `vmkernel.log` file on a release build.

This issue is resolved in this release. The fix restricts `End path evaluation for device` messages to only non-release builds, such as beta. You must enable the VERBOSE log level to see such logs.

PR 3101512: You see a warning for lost uplink redundancy even when the uplink is active

If you quickly remove the network cable from a physical NIC and reinsert it, the ESXi host agent, hostd, triggers an event to restore uplink redundancy, but in some cases, although the uplink restores in a second, you still see a misleading alarm for lost uplink redundancy.

This issue is resolved in this release.

PR 3161473: Operations with stateless ESXi hosts might not pick the expected remote disk for system cache, which causes remediation or compliance issues

Operations with stateless ESXi hosts, such as storage migration, might not pick the expected remote disk for system cache. For example, you want to keep the new boot LUN as LUN 0, but vSphere Auto Deploy picks LUN 1.

This issue is resolved in this release. The fix provides a consistent way to sort the remote disks and always pick the disk with the lowest LUN ID. To make sure you enable the fix, follow these steps:

1. On the Edit host profile page of the Auto Deploy wizard, select **Advanced Configuration Settings** > **SystemImage Cache Configuration** > **System Image Cache Configuration**
2. In the **System Image Cache Profile Settings** drop-down menu, select **Enable stateless caching on the host**.
3. Edit **Arguments** for first disk by replacing **remote** with **sortedremote** and/or **remoteesx** with **sortedremoteesx**.

ESXi-7.0U3o-22348816-no-tools

Profile Name	ESXi-7.0U3o-22348816-no-tools

Related CVE numbers	N/A

This patch updates the following issues:

PR 3187846: Setting the screen resolution of a powered off, encrypted virtual machine does not always work when manually editing the VMX file

If you manually specify the screen resolution of a powered off, encrypted virtual machine by editing the VMX file, the change might not take effect.

This issue is resolved in this release.

PR 3253205: Static IPv6 gateway disappears in 18 hours

If you configure a static IPv6 gateway address in your vSphere environment, such gateways might no longer exist in up to 18 hours due to a timeout.

This issue is resolved in this release. The fix removes the existing timeout for static gateways.

PR 3272532: You see speed as Half Duplex after changing the speed from Auto to Full on a VMNIC

In some cases, length checks during the parsing of duplex TLVs in an environment with active Cisco Discovery Protocol (CDP) might fail. As a result, when you change the speed from **Auto** to **Full** on a physical NIC on peer devices you do not see the real duplex value in the TLV under the neighbor information, but the default Half Duplex value.

This issue is resolved in this release.

PR 3251981: An NFSv4.1 file might appear to be empty even though it contains data

When you open an existing NFSv4.1 file with write only access, if for some reason the NFS client opens again the same file with read only access, read operations from the client might return no data although the file is not empty.

This issue is resolved in this release.

PR 3116601: When you override the default gateway for the vSAN VMkernel adapter on an ESXi host, the vSphere HA agent on the host displays as inaccessible

In some cases, when you override the default gateway for the vSAN VMkernel adapter on an ESXi host, the Fault Domain Manager (FDM), which is the agent that vSphere HA deploys on ESX hosts, might stop receiving Internet Control Message Protocol (ICMP) pings. As a result, FDM might issue false cluster alarms that the vSphere HA agent on the host cannot reach some management network addresses of other hosts.

This issue is resolved in this release.

PR 3251801: vSphere vMotion operation from a 6.7.x ESXi host with an Intel Ice Lake CPU fails with msg.checkpoint.cpucheck.fail

vSphere vMotion operations by using either the vSphere Client or VMware Hybrid Cloud Extension (HCX) from an Intel Ice Lake CPU host running ESXi 6.7.x fails with an error such as `msg.checkpoint.cpucheck.fail`. In the vSphere Client, you see a message that cpuid.PSFD is not supported on the target host. In HCX, you see a report such as `A general system error occurred: vMotion failed:`.

This issue is resolved in this release.

PR 3036883: A SAS path might be lost during upgrade of lsi_msgpt3 drivers

Upgrading `lsi_msgpt3` drivers of version `17.00.12.00-1` and earlier might cause storage connections and VMs on ESXi host to become unresponsive due to a lost SAS path. In the VMkernel logs, you see error messages such as:

```
2022-06-19T05:25:51.949Z cpu26:2097947)WARNING: NMP: nmpDeviceAttemptFailover:640:
Retry world failover device "naa.6000d310045e2c000000000000000043" - issuing command
0x459acc1f5dc0
```

```
2022-06-19T05:25:51.949Z cpu26:2097947)WARNING: vmw_psp_rr: psp_rrSelectPath:2177: Could
not select path for device "naa.6000d310045e2c000000000000000043".
```

```
2022-06-19T05:25:51.949Z cpu26:2097947)WARNING: NMP: nmpDeviceAttemptFailover:715: Retry
world failover device "naa.6000d310045e2c000000000000000043" - failed to issue command due
to Not found (APD), try again...
```

This issue is resolved in this release. If you already face the issue, rescan your storage after failing back on storage controller to recover the paths and storage connections.

PR 3224739: You see alarms for dropped syslog messages

If the network throughput of your vSphere system does not align with the speed at which log messages are generated, some of the log messages sent to the remote syslog server might drop. As a result, in the vSphere Client you see host errors of type `Triggered Alarm` and in the logs, you see warnings such as `ALERT: vmsyslog logger xxxx:514 lost yyyy log messages`.

This issue is resolved in this release. The fix improves the network logging performance of the logging service to reduce the number of such lost log messages.

PR 3247027: If any failure occurs during a vSphere vMotion migration of NVIDIA virtual GPU (vGPU) VM, the destination ESXi host might fail with a purple diagnostic screen

In very rare cases, if any type of failure occurs during a vSphere vMotion migration of a vGPU VM, the vMotion operation is marked as a failure while a specific internal operation is in progress. As a result, the destination ESXi host might fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3095511: The SFCB service intermittently fails and generates "sfcb-vmware_bas-zdump" files on multiple ESXi hosts

In very rare cases, when the SFCB service tries to access an uninitialized variable, the service might fail with dump file such as `sfcb-vmware_bas-zdump.000` . The issue occurs because accessing an uninitialized variable can cause the SFCB process to keep requesting memory until it exceeds the heap allocation.

This issue is resolved in this release.

PR 3218578: You see wrong device descriptions of some Lenovo ThinkSystem boot RAID adapters

In a vSphere client interface, such as the vSphere Client, or when you run commands such as `lspci` and `esxcfg-scsidevs -a` from the ESXi shell, you might see the device names of some Lenovo-branded boot SATA/NVMe adapters as the generical names of the controller chips they use. For example, **Lenovo ThinkSystem M.2 with Mirroring Enablement Kit** is displayed as **88SE9230 PCIe SATA 6GB/s controller**.

This issue is resolved in this release.

PR 3256804: File server loses connectivity after failover when running vSAN File Service on NSX overlay network

If vSAN File Service is running on an NSX overlay network, the file server might lose connectivity after it fails over from one agent VM to another agent VM. The file server can failover when reconfiguring file service domain from such without Active Directory(AD) to such with AD, or if vSAN detects unhealthy behavior in the file server, file share, or AD server. If file server connectivity is lost after a failover, File Service clients cannot access the file share. The following health warning might be reported:

```
One or more DNS servers is not reachable.
```

This issue is resolved in this release.

PR 3217633: vSAN management service on the orchestration host malfunctions during vCenter restart

This issue can occur on vSAN clusters where vCenter is deployed. If multiple cluster shutdown operations are performed, the `/etc/vmware/vsan/vsanperf.conf` file on the orchestration host can contain two versions of the following management VM: `vc_vm_moIdvc_vm_moid` . These configuration options conflict with each other and can cause the vSAN management service to malfunction.

This issue is resolved in this release.

PR 3224306: When you change the ESXi syslog setting syslog.global.logDir, if syslog.global.logDirUnique is active, you might see 2 levels of <hostname> subdir under the logdir path

After upgrading an ESXi host to 7.0 Update 3c and later, if you change the syslog setting `syslog.global.logDir` and the `syslog.global.logDirUnique` setting is active, you might see 2 levels of `<hostname>` subdirs under the `logdir` path on the host. The `syslog.global.logDirUnique` setting is useful if the same NFS directory is configured as the `Syslog.global.LogDir` by multiple ESXi hosts, as it creates a subdirectory with the name of the ESXi host under `logdir` .

This issue is resolved in this release.

PR 3223755: ESXi syslog daemon fails to resume transmitting logs to the configured SSL remote syslog server once a drop in the network connectivity restores

If a remote SSL syslog server temporarily loses connectivity, the ESXi syslog daemon might fail to resume transmitting logs after connectivity restores and you must restart the service to re-activate transmissions. The issue occurs due to some unhandled exceptions while the ESXi syslog daemon tries to restore connection to the SSL remote syslog server.

This issue is resolved in this release. The fix adds a generic catch for all unhandled exceptions.

PR 3185536: vSAN cluster remediation error after vCenter upgrade to 7.0 Update 3

When you upgrade vCenter from version 6.5.x to 7.0 Update 3, and reconfigure the vSAN cluster, a vSAN cluster remediation is triggered, but in some cases fails.

This issue is resolved in this release.

PR 3110401: The Explicit Congestion Notification (ECN) setting is not persistent on ESXi host reboot

ECN, specified in RFC 3168, allows a TCP sender to reduce the transmission rate to avoid packet drops and is activated by default. However, if you change the default setting, or manually deactivate ECN, such changes to the ESXi configuration might not persist after a reboot of the host.

This issue is resolved in this release.

PR 3153395: Upon refresh, some dynamic firewalls rules might not persist and lead to vSAN iSCSI Target service failure

If you frequently run the command `esxcli network firewall refresh` , a race condition might cause some dynamic firewalls rules to be removed upon refresh or load. As a result, some services such as the vSAN iSCSI Target daemon, which provides vSAN storage with iSCSI protocol, might fail.

This issue is resolved in this release.

PR 3096769: You see high latency for VM I/O operations in a vSAN cluster with Unmap activated

This issue affects vSAN clusters with Unmap activated. A problem in Unmap handling in LSOM creates log congestion. The log congestion can cause high VM I/O latency.

This issue is resolved in this release.

PR 3163361: The Audit Record Storage Capacity parameter does not persist across ESXi host reboots

After an ESXi host reboot, you see the **Audit Record Storage Capacity** parameter restored to the default value of 4 MiB, regardless of any previous changes.

This issue is resolved in this release.

PR 3162496: If the Internet Control Message Protocol (ICMPA) is not active, ESXi host reboot might take long after upgrading to vSphere 8.0 and later

If ICMPA is not active on the NFS servers in your environment, after upgrading your system to vSphere 8.0 and later, ESXi hosts reboot might take an hour to complete, because restore operations for NFS datastores fail. NFS uses the `vmkping` utility to identify reachable IPs of the NFS servers before executing a mount operation and when ICMP is not active, mount operations fail.

This issue is resolved in this release. To remove dependency on the ICMP protocol to find reachable IPs, the fix adds socket APIs to ensure that IPs on a given NFS server are available.

PR 3220004: VBS-enabled Windows VMs might fail with a blue diagnostic screen when an ESXi host is under memory pressure

Windows VMs with virtualization-based security (VBS) enabled might intermittently fail with a blue diagnostic screen during memory-heavy operations such as deleting snapshots or consolidating disks. The BSOD has the following signature:

```
DRIVER_VERIFIER_DMA_VIOLATION (e6)
An illegal DMA operation was attempted by a driver being verified.
```

Arguments:

```
Arg1: 0000000000000026, IOMMU detected DMA violation.
Arg2: 0000000000000000, Device Object of faulting device.
Arg3: xxxxxxxxxxxxxxxx, Faulting information (usually faulting physical address).
Arg4: 0000000000000008, Fault type (hardware specific).
```

This issue is resolved in this release.

PR 3162905: ESXi hosts might intermittently disconnect from vCenter in case of memory outage

In rare cases, if vCenter fails to allocate or transfer active bitmaps due to an alert for insufficient memory for any reason, the hostd service might repeatedly fail and you cannot reconnect the host to the vCenter.

This issue is resolved in this release. The fix makes sure that in such cases you see an error rather than the hostd service failure.

PR 3108979: Staging ESXi patches and ESXi upgrade tasks might become indefinitely unresponsive due to a log buffer limit

If a large string or log exceed the python log buffer limit of 16K, the logger becomes unresponsive. As a result, when you stage ESXi patches on a host by using the vSphere Client, the process responsible for completing the staging task on ESXi might become indefinitely unresponsive. The task times out and reports an error. The issue occurs also when you remediate ESXi hosts by using a patch baseline.

This issue is resolved in this release. The fix breaks the large input string into smaller chunks for logging.

PR 3219264: vSAN precheck for maintenance mode or disk decommission doesn't list objects that might lose accessibility

This issue affects objects with resyncing components, and some components reside on a device to be removed or placed into maintenance mode. When you run a precheck with the **No-Action** option, the precheck does not evaluate the object correctly to report it in the `inaccessibleObjects` list.

This issue is resolved in this release. Precheck includes all affected objects in the `inaccessibleObjects` list.

PR 3186545: Vulnerability scans might report the HTTP TRACE method on vCenter ports 9084 and 9087 as vulnerable

Some third-party tools for vulnerability scans might report the HTTP TRACE method on vCenter ports 9084 and 9087 as vulnerable.

This issue is resolved in this release.

PR 3221591: ESXi NVMe/TCP initiator fails to recover paths after target failure recovery

When a NVMe/TCP target recovers from a failure, ESXi cannot recover the path.

This issue is resolved in this release.

PR 3186351: You see an override flag of NIC teaming, security, or traffic shaping policy on a portgroup unexpectedly enabled post an ESXi host reboot

In some cases, a networking configuration might not persist in the ESXi ConfigStore and you see an override flag of NIC teaming, security, or traffic shaping policy on a portgroup unexpectedly enabled post an ESXi host reboot.

This issue is resolved in this release.

PR 3162790: The sfcb daemon might fail with a core dump while installing a third-party CIM provider

The sfcb daemon might try to access already freed memory when registering a CIM provider and fail with a core dump while installing a third-party CIM provider, such as Dell OpenManage Server Administrator for example.

This issue is resolved in this release.

PR 3157195: ESX hosts might fail with a purple diagnostic screen and an error NMI IPI: Panic requested by another PCPU

The resource pool cache is a VMFS specific volume level cache that stores the resource clusters corresponding to the VMFS volume. While searching for priority clusters, the cache flusher workflow iterates through a large list of cached resource clusters, which can cause lockup of the physical CPUs. As a result, ESX hosts might fail with a purple diagnostic screen. In the `logDump` file, you see an error such as:

```
^[[7m2022-10-22T07:56:47.322Z cpu13:2101160)WARNING: Heartbeat: 827: PCPU 0 didn't have a heartbeat for 7 seconds, timeout is 14, 1 IPIs sent; *may* be locked up.^[[0m^
```

```
[[31;1m2022-10-22T07:56:47.322Z cpu0:2110633)ALERT: NMI: 710: NMI IPI: RIPOFF(base):RBP:CS
```

This issue is resolved in this release.

PR 3230493: If a delta sync runs while the target vSphere Replication server is not active, Windows virtual machines might become unresponsive

If the target Sphere Replication server is not active during a delta sync, the synchronization process cannot complete and Windows virtual machines become unresponsive.

This issue is resolved in this release. The fix makes sure that no delta sync jobs start when a Sphere Replication server is not active.

PR 3122037: ESXi ConfigStore database fills up and writes fail

Stale data related to block devices might not be deleted in time from the ESXi ConfigStore database and cause an out of space condition. As a result, write operations to ConfigStore start to fail. In the backtrace, you see logs such as:

```
2022-12-19T03:51:42.733Z cpu53:26745174)WARNING: VisorFSRam: 203: Cannot extend visorfs file /etc/vmware/configstore/current-store-1-journal because its ramdisk (configstore) is full .
```

This issue is resolved in this release.

PR 3246132: You see a system clock drift on an ESXi host after synchronization with the NTP server fails

If connectivity between the NTP server and an ESXi host is delayed for some reason, the system clock on the ESXi host might experience a drift. When you run the `vsish` command `vsish -e get /system/ntpclock/clockData` , you might see a large negative value for the `adjtime` field. For example:

```
NTP clock data {
...  adjtime() (usec):-309237290312 <<<<<<
...
}
```

This issue is resolved in this release.

PR 3185560: vSphere vMotion operations for virtual machines with swap files on a vSphere Virtual Volumes datastore intermittently fail after a hot extend of the VM disk

vSphere vMotion operations for virtual machines with swap files on a vSphere Virtual Volumes datastore might fail under the following circumstances:

A VM that runs on ESXi host A is migrated to ESXi host B, then the VM disk is hot extended, and the VM is migrated back to ESXi host A. The issue occurs due to stale statistics about the swap virtual volume.

This issue is resolved in this release.

PR 3236207: You cannot unmount an NFS v3 datastore from a vCenter system because the datastore displays as inaccessible

While unmounting an NFSv3 datastore from a vCenter system by using either the vSphere Client or ESXCLI, you might see the datastore either as inaccessible, or get an `Unable to Refresh` error. The issue occurs when a hostd cache refresh happens before NFS deletes the mount details from ConfigStore, which creates a rare race condition.

This issue is resolved in this release.

PR 3236064: Compliance or remediation scans by using vSphere Lifecycle Manager might take long on ESXi hosts with a large number of datastores

Compliance or remediation scans by using vSphere Lifecycle Manager include an upgrade precheck that lists all volumes attached to an ESXi host, their free space, versions, and other details. If a host has many datastores attached, each with a large capacity, the precheck can take long. The time is multiplied by the number of baselines attached to the cluster or host.

This issue is resolved in this release. If you already face the issue, disconnect the attached datastores while performing the remediation or compliance scans and reattach them after the operations complete.

PR 3245763: During a vSphere vMotion operation, destination ESXi hosts with a Distributed Firewall (DFW) enabled might fail with a purple diagnostic screen

If the destination host in a vSphere vMotion operation has a DFW enabled, a rare race condition might cause the host to fail with a purple diagnostic screen.

This issue is resolved in this release.

PR 3158866: Virtual machines might become unresponsive during VMFS volume expansion due to a Logical Volume Manager (LVM) check

If a VMFS volume expansion operation happens during a LVM probe to update volume attributes, such as the size of the VMFS partition backing of the VMFS volume, the current size of the VMFS volume might not match the LVM metadata on the disk. As a result, LVM marks such a volume offline and virtual machines on that volume become unresponsive.

This issue is resolved in this release. The fix improves Input Output Control (IOCTL) to speed up the update of device attributes and avoid such cases.

PR 3152717: vSphere Auto Deploy workflows might fail after an upgrade to vCenter Server 7.0 Update 3j or later

Due to a networking issue in reverse proxy configuration environments, vSphere Auto Deploy workflows might fail after an upgrade to vCenter Server 7.0 Update 3j or later. In the ESXi management console and in the `/var/log/vmware/rbd/rbd-cgi.log file` you see an HTTP client error.

This issue is resolved in this release. The fix makes sure Auto Deploy workflows run successfully in reverse proxy configuration environments.

PR 3185125: Virtual SLIT table not populated for the guest OS when using sched.nodeX.affinity

When you specify virtual NUMA node affinity, the vSLIT table might not be populated and you see the following error in `vmware.log`: `vSLIT: NumaGetLatencyInfo failed with status: 195887107.`

This happens when setting node affinity as follows:

```
numa.slit.enable = "TRUE"

sched.node0.affinity = 0

sched.node1.affinity = 1

...sched.nodeN.affinity = N
```

This issue is resolved in this release. If you already face the issue, specify VCPU affinity to physical CPUs on the associated NUMA nodes, instead of node affinity.

For example:

```
numa.slit.enable = "TRUE"

sched.vcpu0.affinity = "0-7"

sched.vcpu1.affinity = "0-7"

...sched.vcpuN.affinity = "Y-Z"
```

PR 3181774: You do not see an error when you attach a CBT enabled FCD to a VM with CBT disabled

Attaching a First Class Disk (FCD) with Changed Block Tracking (CBT) to a VM with CBT disabled does not throw a detailed error, but the operation cannot take effect. In the backtrace, you might see an error message such as `InvalidState` , which is generic and does not provide details on the issue.

This issue is resolved in this release. The fix adds the error message `Cannot attach a CBT enabled fcd: {path} to CBT disabled VM.` to the logs of the hostd service and adds a status message for the task in the vSphere Client.

PR 3185827: You see trap files in a SNMP directory under /var/spool even though SNMP is not enabled

After the hostd service starts, for example after an ESXi host reboot, it might create a SNMP directory under `/var/spool` and you see many `.trp` files to pile in this directory.

This issue is resolved in this release. The fix makes sure that the directory `/var/spool/snmp` exists only when SNMP is enabled.

PR 3082867: An ESXi host might fail with a purple diagnostic screen after a replicated virtual machine migrates to the host

In some environments, when a replicated virtual machine migrates to a certain ESXi host, during a full sync, some `SCSI WRITE` commands might target address ranges past the end of the transfer map. As a result, the ESXi host might fail with a purple diagnostic screen and a backtrace such as:

```
#0 DLM_free (msp=0x43238f2c9cc0, mem=mem@entry=0x43238f6db860, allowTrim=allowTrim@entry=1
'\001') at bora/vmkernel/main/dlmalloc.c:4924

#1 0x000041802a151e01 in Heap_Free (heap=0x43238f2c9000, mem=<optimized out>) at bora/
vmkernel/main/heap.c:4217

#2 0x000041802a3b0fa1 in BitVector_Free (heap=<optimized out>, bv=<optimized out>) at
bora/vmkernel/util/bitvector.c:94

#3 0x000041802b9f4f3f in HbrBitmapFree (bitmap=<optimized out>) at bora/modules/vmkernel/
hbr_filter/hbr_bitmap.c:91
```

This issue is resolved in this release.

PR 3162499: During service insertion for NSX-managed workload VMs, some VMS might become intermittently unresponsive, and the virtual device might reset

During service insertion for NSX-managed workload VMs, a packet list might be reinjected from the input chain of one switchport to another switchport. In such cases, the source switchport does not correspond to the actual `portID` of the input chain and the virtual device does not get completion status for the transmitted frame. As a result, when you run a service insertion task, some VMs might become intermittently unresponsive due to network connectivity issues.

This issue is resolved in this release.

PR 3219441: You cannot send keys to a guest OS by using the browser console in the ESXi Host Client

In the ESXi Host Client, when you open the browser console of a virtual machine and select **Guest OS > Send keys**, when you select a key input, for example **Ctrl-Alt-Delete**, the selection is not sent to the guest OS.

This issue is resolved in this release.

PR 3209853: Windows VMs might fail with a blue diagnostic screen with 0x5c signature due to platform delays

Windows VMs might fail with a blue diagnostic screen with the following signature due to a combination of factors involving the Windows timer code and platform delays, such as storage or network delays:

`HAL_INITIALIZATION_FAILED (0x5c)` (This indicates that the HAL initialization failed.)

Arguments:

```
Arg1: 0000000000000115, HAL_TIMER_INITIALIZATION_FAILURE
Arg2: fffff7ea800153e0, Timer address
Arg3: 00000000000014da, Delta in QPC units (delta to program the timer with)
Arg4: ffffffffc0000001, invalid status code (STATUS_UNSUCCESSFUL)
```

Checks done by HPET timers in Windows might fail due to such platform delays and cause the issue.

This issue is resolved in this release.

PR 3178109: vSphere Lifecycle Manager compliance check fails with "An unknown error occurred while performing the operation"

The base ESXi image contains driver components that can be overridden by higher version async driver components packaged by an OEM add-on. If such a component is manually removed on a host, the compliance check of the vSphere Lifecycle Manager might fail unexpectedly. In the vSphere Client, you see errors such as `Host status is unknown` and `An unknown error occurred while performing the operation.`

This issue is resolved in this release.

PR 3180634: Performance of certain nested virtual machines on AMD CPUs might degrade

Nested virtual machines on AMD CPUs with operational systems such as Windows with virtualization-based security (VBS) might experience performance degradation, timeouts, or unresponsiveness due to an issue with the virtualization of AMD's Rapid Virtualization Indexing (RVI), also known as Nested Page Tables (NPT).

This issue is resolved in this release.

PR 3223539: Some vmnics might not be visible after an ESXi host reboot due to a faulty NVMe device

If an NVMe device fails during the attach phase, the NVMe driver disables the NVMe controller and resets the hardware queue resources. When you try to re-attach the device, a mismatch between the hardware and driver queue pointers might cause an IOMMU fault on the NVMe device, which leads to memory corruption and failure of the vmkdevmgr service. As a result, you do not see some vmnics in your network.

This issue is resolved in this release.

PR 3218835: When you disable or suspend vSphere Fault Tolerance, virtual machines might become unresponsive for about 10 seconds

When you disable or suspend vSphere FT, some virtual machines might take about 10 seconds to release vSphere FT resources. As a result, such VMs become temporarily unresponsive to network requests or console operations.

This issue is resolved in this release.

PR 3181901: ESXi host becomes unresponsive and you cannot put the host in Maintenance Mode or migrate VMs from that host

Asynchronous reads of metadata on a VMFS volume attached to an ESXi host might cause a race condition with other threads on the host and make the host unresponsive. As a result, you cannot put the host in Maintenance Mode or migrate VMs from that host.

This issue is resolved in this release.

PR 3156666: Packets with length less than 60 bytes might drop

An ESXi host might add invalid bytes, other than zero, to packets with less than 60 bytes. As a result, packets with such invalid bytes drop.

This issue is resolved in this release.

PR 3180283: When you migrate a VM with recently hot-added memory, an ESXi host might repeatedly fail with a purple diagnostic screen

Due to a race condition while the memory hotplug module recomputes the NUMA memory layout of a VM on a destination host after migration, an ESXi host might repeatedly fail with a purple diagnostic screen. In the backtrace, you see errors such as:

```
0x452900262cf0:[0x4200138fee8b]PanicvPanicInt@vmkernel#nover+0x327 stack: 0x452900262dc8,

```

This issue is resolved in this release.

PR 3100552: ESXi booting times out after five minutes and the host automatically reboots

During initial ESXi booting, when you see the **Loading VMware ESXi** progress bar, if the bootloader takes more than a total of five minutes to load all the boot modules before moving on to the next phase of booting, the host firmware times out the boot process and resets the system.

This issue is resolved in this release. With ESXi 7.0 Update 3o, the ESXi bootloader resets the five-minute timeout after each boot module loads.

PR 3184368: The durable name of a SCSI LUN might not be set

The durable name property for a SCSI-3 compliant device comes from pages `80h` and `83h` of the Vital Product Data (VPD) as defined by the T10 and SMI standards. To populate the durable name, ESXi first sends an inquiry command to get a list of VPD pages supported by the device. Then ESXi issues commands to get data for all supported VPD pages. Due to an issue with the target array, the device might fail a command to get VPD page data for a page in the list with a `not supported` error. As a result, ESXi cannot populate the durable name property for the device.

This issue is resolved in this release. The fix ignores the error on command to get VPD page data, except pages `80h` and `83h` , if that data is not required for the generation of durable name.

PR 3184425: Port scan of a VXLAN Tunnel End Point (VTEP) on an ESXi host might result in an intermittent connectivity loss

Port scan of a VTEP on an ESXi host might result in an intermittent connectivity loss, but only under the following conditions:

1. Your environment has many VTEPs
2. All VTEPs are in the same IP subnet
3. The upstream switch is Cisco ACI

This issue is resolved in this release.

PR 3156627: Changing the mode of the virtual disk on a running virtual machine might cause the VM to fail

If you use the VMware Host Client to edit the disk mode of a running virtual machine, for example from Independent - Nonpersistent to Dependent or Independent - Persistent, the operation fails and might cause the VM to fail. In the `vmware.log` , you see errors such as:

```
msg.disk.notConfigured2] Failed to configure disk 'scsi0:4'. The virtual machine cannot be powered on with an unconfigured disk.
```

```
[msg.checkpoint.continuesync.error] An operation required the virtual machine to quiesce and the virtual machine was unable to continue running.
```

This issue is resolved in this release. The fix blocks changing the mode of an Independent - Nonpersistent disk on a running virtual machine by using the VMware Host Client. The vSphere Client already blocks such operations.

PR 3164477: In VMware Skyline Health Diagnostics, you see multiple warnings for vSAN memory pools

The free heap memory estimation logic for some vSAN memory pools might consider more memory heap than actual and trigger warnings for insufficient memory. As a result, you see `Memory pools (heap)` health warnings for many hosts under the **Physical disks** section in Skyline Health.

This issue is resolved in this release.

PR 3168950: ESXi hosts fail with a purple diagnostic screen while installing VMware NSX-T Data Center due to insufficient TCP/IP heap space

VMware NSX-T Data Center has multiple net stacks and the default TCP/IP heap space might not be sufficient for installation. As a result, ESXi hosts might fail with a purple diagnostic screen.

This issue is resolved in this release. The fix increases the default `TcpipHeapSize` setting to 8 MB from 0 MB and the maximum size to 128 MB from 32 MB. In the vSphere Client, you can change the `TcpipHeapSize` value by navigating to **Hosts and Clusters > Configure > System > Advanced System Settings > TcpipHeadSize**. In vCenter systems with VMware NSX-T Data Center, set the value to 128 MB.

PR 3096974: Rare race condition in I/O filters might cause an ESXi host to fail with a purple diagnostics screen

ESXi hosts in which virtual machines use I/O filters might randomly fail with a purple diagnostics screen and an error such as `#DF Exception 8 IP 0x42002c54b19f SP 0x453a9e8c2000` due to a rare race condition.

This issue is resolved in this release.

PR 3112194: Spherelet might fail to start on an ESXi host due to the execInstalledOnly setting

The `execInstalledOnly` setting is a run time parameter which limits execution of binaries such as applications and vmkernel modules to improve security and guard against breaches and compromises. Some `execInstalledOnly` security checks might interfere with Spherelet, the ESXi UserWorld agent that acts as an extension to the Kubernetes Control Plane, and prevent it to start, even when all files are installed.

This issue is resolved in this release.

PR 3115870: VMware VIB installation might fail during concurrent vendor package installations

When you install update packages from several vendors, such as JetStream Software, Microsoft, and VMware, multiple clients call the same PatchManager APIs and might lead to a race condition. As a result, VMware installation packages

(VIBs) might fail to install. In the logs, you see an error such as `vim.fault.PlatformConfigFault`, which is a catch-all fault indicating that some error has occurred regarding the configuration of the ESXi host. In the vSphere Client, you see a message such as `An error occurred during host configuration.`

This issue is resolved in this release. The fix is to return a `TaskInProgress` warning instead of `PlatformConfigFault`, so that you are aware of the actual issue and retry the installation.

PR 3164439: Certain applications might take too many ESXi file handles and cause performance aggravation

In very rare cases, applications such as NVIDIA virtual GPU (vGPU) might consume so many file handles that ESXi fails to process other services or VMs. As a result, you might see GPU on some nodes to disappear, or report zero GPU memory, or performance degradation.

This issue is resolved in this release. The fix reduces the number of file handles a vGPU VM can consume.

PR 3162963: If parallel volume expand and volume refresh operations on the same VMFS volume run on two ESXi hosts in the same cluster, the VMFS volume might go offline

While a VMFS volume expand operation is in progress on an ESXi host in a vCenter cluster, if on another host a user or vCenter initiates a refresh of the same VMFS volume capacity, such a volume might go offline. The issue occurs due to a possible mismatch in the device size, which is stamped on the disk in the volume metadata during a device rescan, and the device size value in the Pluggable Storage Architecture (PSA) layer on the host, which might not be updated if the device rescan is not complete.

This issue is resolved in this release. The fix improves the resiliency of the volume manager code to force a consecutive refresh of the device attributes and comparison of the device sizes again if vCenter reports a mismatch in the device size.

PR 3161690: CPU usage of ESXi hosts might intermittently increase in environments that use a Vigor router

Due to a rare race condition, when a VM power off command conflicts with a callback function by a Vigor router, you might see increased CPU usage on ESXi hosts, for example, after an upgrade.

This issue is resolved in this release.

PR 3165374: ESXi hosts might become unresponsive and fail with a purple diagnostic screen during TCP TIME_WAIT

The TCP slow timer might starve TCP input processing while it covers the list of connections in `TIME_WAIT` closing expired connections due to contention on the global TCP pcbinfo lock. As a result, the VMkernel might fail with a purple diagnostic screen and the error `Spin count exceeded - possible deadlock` while cleaning up `TCP TIME_WAIT` sockets. The backtrace points to tcpip functions such as `tcp_slowtimo()` or `tcp_twstart()`.

This issue is resolved in this release. The fix adds a new global lock to protect the list of connections in `TIME_WAIT` and to acquire the TCP pcbinfo lock only when closing an expired connection.

PR 3166818: If any of the mount points that use the same NFS server IP returns an error, VAAI-NAS might mark all mount points as not supported

When you use a VAAI-NAS vendor plug-in, multiple file systems on an ESXi host use the same NFS server IP to create a datastore. For certain NAS providers, if one of the mounts returns a `VIX_E_OBJECT_NOT_FOUND (25)` error during the `startSession` call, hardware acceleration for all file systems with the same NFS server IP might become unsupported. This issue occurs when an ESXi host mounts a directory on an NFS server, but that directory is not available at the time of the `startSession` call, because, for example, it has been moved from that NFS server.

This issue is resolved in this release. The fix makes sure that VAAI-NAS marks as not supported only mounts that report an error.

PR 3112692: The smartpqi driver cannot get the location of ThinkSystem PM1645a SAS SSD devices

In rare cases, the `smartpqi plugin in LSU service` might get a longer serial number string from the VPD page 0x80 than the actual serial number, and the device lookup in the cache fails. As a result, when you run the command

`esxcli storage core device physical get -d <device_id>` to get a device location, you see an error such as `Unable to get location for device. Device is not found.`.

This issue is resolved in this release. The fix makes sure that the `smartpqi plugin in LSU service` always checks the correct serial number length and finds the device location.

PR 3100030: An ESXi host fails with a purple diagnostic screen indicating VMFS heap corruption

A race condition in the host cache of a VMFS datastore might cause heap corruption and the ESXi host fails with a purple diagnostic screen and a message such as:

`PF Exception 14 in world xxxxx:res3HelperQu IP 0xxxxxxe2 addr 0xXXXXXXXXX`

This issue is resolved in this release.

PR 3121216: If the Internet Control Message Protocol (ICMPA) is not active, ESXi host reboot might take long after an upgrade

If ICMPA is not active on the NFS servers in your environment, after upgrading your system, ESXi hosts reboot might take an hour to complete, because restore operations for NFS datastores fail. NFS uses the `vmkping` utility to identify reachable IPs of the NFS servers before executing a mount operation and when ICMP is not active, mount operations fail.

This issue is resolved in this release. To remove dependency on the ICMP protocol to find reachable IPs, the fix adds socket APIs to ensure that IPs on a given NFS server are available.

PR 3098760: ESXi hosts randomly disconnect from the Active Directory domain or vCenter due to Likewise memory exhaustion

Memory leaks in Active Directory operations and related libraries, or when smart card authentication is enabled on an ESXi host, might lead to Likewise memory exhaustion.

This issue is partially resolved in this release. For more information, see VMware knowledge base article 78968.

PR 3118402: The NTP monitoring function returns intermittent time sync failure in the time services test report even when the ESXi host system clock is actually in sync

The time services monitoring infrastructure periodically queries the NTP daemon, ntpd, for time sync status on ESXi hosts. Intermittent query failures might occur due to timeouts in the socket call to read such status information. As a result, you might see time sync failure alerts in the NTP test reports.

This issue is resolved in this release. The fix makes sure that NTP monitoring queries do not fail.

PR 3159168: You see multiple "End path evaluation for device" messages in the vmkernel.log

A periodic device probe that evaluates the state of all the paths to a device might create multiple unnecessary `End path evaluation for device` messages in the `vmkernel.log` file on a release build.

This issue is resolved in this release. The fix restricts `End path evaluation for device` messages to only non-release builds, such as beta. You must enable the VERBOSE log level to see such logs.

PR 3101512: You see a warning for lost uplink redundancy even when the uplink is active

If you quickly remove the network cable from a physical NIC and reinsert it, the ESXi host agent, hostd, triggers an event to restore uplink redundancy, but in some cases, although the uplink restores in a second, you still see a misleading alarm for lost uplink redundancy.

This issue is resolved in this release.

PR 3161473: Operations with stateless ESXi hosts might not pick the expected remote disk for system cache, which causes remediation or compliance issues

Operations with stateless ESXi hosts, such as storage migration, might not pick the expected remote disk for system cache. For example, you want to keep the new boot LUN as LUN 0, but vSphere Auto Deploy picks LUN 1.

This issue is resolved in this release. The fix provides a consistent way to sort the remote disks and always pick the disk with the lowest LUN ID. To make sure you enable the fix, follow these steps:

1. On the Edit host profile page of the Auto Deploy wizard, select **Advanced Configuration Settings** > **SystemImage Cache Configuration** > **System Image Cache Configuration**
2. In the **System Image Cache Profile Settings** drop-down menu, select **Enable stateless caching on the host**.
3. Edit **Arguments** for first disk by replacing **remote** with **sortedremote** and/or **remoteesx** with **sortedremoteesx**.

ESXi-7.0U3so-22348808-standard

Profile Name	ESXi-7.0U3so-22348808-standard
Build	For build information, see Patches Contained in This Release.
Vendor	VMware, Inc.
Release Date	September 28, 2023
Acceptance Level	PartnerSupported
Affected Hardware	N/A
Affected Software	N/A

This patch updates the following issues:

ESXi 7.0 Update 3o provides the following security updates:

- The cURL library is updated to version 8.1.2.
- The ESXi userworld libxml2 library is updated to version 2.10.4.
- The SQLite library is updated to version 3.42.0.
- The OpenSSL package is updated to version 1.0.2zh.

The cpu-microcode VIB includes the following AMD microcode:

The following VMware Tools ISO images are bundled with ESXi 7.0 Update 3o:

- **windows.iso**: VMware Tools 12.2.6 supports Windows 7 SP1 or Windows Server 2008 R2 SP1 and later.
- **linux.iso**: VMware Tools 10.3.25 ISO image for Linux OS with **glibc** 2.11 or later.

The following VMware Tools ISO images are available for download:

- VMware Tools 11.0.6:
  - **windows.iso**: for Windows Vista (SP2) and Windows Server 2008 Service Pack 2 (SP2).
- VMware Tools 10.0.12:
  - **winPreVista.iso**: for Windows 2000, Windows XP, and Windows 2003.
  - **linuxPreGLibc25.iso**: supports Linux guest operating systems earlier than Red Hat Enterprise Linux (RHEL) 5, SUSE Linux Enterprise Server (SLES) 11, Ubuntu 7.04, and other distributions with **glibc** version earlier than 2.5.
- **solaris.iso**: VMware Tools image 10.3.10 for Solaris.
- **darwin.iso**: Supports Mac OS X versions 10.11 and later. VMware Tools 12.1.0 was the last regular release for macOS. For more details, see VMware knowledge base article 88698.

Follow the procedures listed in the following documents to download VMware Tools for platforms not bundled with ESXi:

- Updating VMware Tools
- VMware Tools for hosts provisioned with Auto Deploy
- What Every vSphere Admin Must Know About VMware Tools
- Earlier versions of VMware Tools
- VMware Tools 12.2.6 Release Notes

The cpu-microcode VIB includes the following Intel microcode:

ESXi-7.0U3so-22348808-no-tools

Profile Name	ESXi-7.0U3so-22348808-no-tools
Build	For build information, see Patches Contained in This Release.
Vendor	VMware, Inc.
Release Date	September 28, 2023
Acceptance Level	PartnerSupported
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_bootbank_vsanhealth_7.0.3-0.100.22348808 • VMware_bootbank_crx_7.0.3-0.100.22348808 • VMware_bootbank_vdfs_7.0.3-0.100.22348808 • VMware_bootbank_esxio-combiner_7.0.3-0.100.22348808 • VMware_bootbank_native-misc-drivers_7.0.3-0.100.22348808 • VMware_bootbank_esx-base_7.0.3-0.100.22348808 • VMware_bootbank_esx-dvfilter-generic-fastpath_7.0.3-0.100.22348808 • VMware_bootbank_cpu-microcode_7.0.3-0.100.22348808 • VMware_bootbank_bmcal_7.0.3-0.100.22348808 • VMware_bootbank_esx-ui_2.11.2-21988676 • VMware_bootbank_gc_7.0.3-0.100.22348808 • VMware_bootbank_trx_7.0.3-0.100.22348808

	• VMware_bootbank_vsan_7.0.3-0.100.22348808 • VMware_bootbank_esx-xserver_7.0.3-0.100.22348808 • VMware_bootbank_loadesx_7.0.3-0.100.22348808 • VMware_bootbank_esx-update_7.0.3-0.100.22348808
PRs Fixed	3219441, 3239369, 3236018, 3232099, 3232034, 3222887, 3217141, 3213025, 3187868, 3186342, 3164962, 3089785, 3160789, 3098679, 3089785, 3256457
Related CVE numbers	N/A

This patch updates the following issues:

ESXi 7.0 Update 3o provides the following security updates:

- The cURL library is updated to version 8.1.2.
- The ESXi userworld libxml2 library is updated to version 2.10.4.
- The SQLite library is updated to version 3.42.0.
- The OpenSSL package is updated to version 1.0.2zh.

The cpu-microcode VIB includes the following AMD microcode:

ESXi7.0U3o - 22348816

Name	ESXi
Version	ESXi7.0U3o - 22348816
Release Date	September 28, 2023
Category	Bugfix
Affected Components	• ESXi Component - core ESXi • ESXi Install/Upgrade • VMware Native AHCI Driver • SMARTPQI LSU Management Plugin • Non-Volatile memory controller driver • Avago (LSI) Native 12Gbps SAS MPT Driver • Intel NVME Driver with VMD Technology
PRs Fixed	3244098, 3216958, 3245763, 3242021, 3246132, 3253205, 3256804, 3239170, 3251981, 3215370, 3117615, 3248478, 3252676, 3235496, 3238026, 3236064, 3224739, 3224306, 3223755, 3216958, 3233958, 3185125, 3219264, 3221620, 3218835, 3185560, 3221099, 3211625, 3221860, 3228586, 3224604, 3223539, 3222601, 3217258, 3213041, 3216522, 3221591, 3216389, 3220004, 3217633, 3216548, 3216449, 3156666, 3181574, 3180746, 3155476, 3211807, 3154090, 3184008, 3183519, 3183519, 3209853, 3100552, 3187846, 3113263, 3176350, 3185827, 3095511, 3184425, 3186351, 3186367, 3154090, 3158524, 3181601, 3180391, 3180283, 3184608, 3181774, 3155476, 3163361, 3182978, 3184368, 3160456, 3164575, 3181901, 3184871, 3166818, 3157195,

	3164355, 3163271, 3112194, 3161690, 3261925, 3178589, 3178721, 3162963, 3168950, 3159168, 3158491, 3158866, 3096769, 3165374, 3122037, 3098760, 3164439, 3161473, 3162790, 3100030, 3096974, 3161473, 3165651, 3083007, 3118240, 3151076, 3118402, 3160480, 3156627, 3158531, 3162499, 3158512, 3053430, 3153395, 3117615, 3099192, 3158508, 3115870, 3119834, 3158220, 3110401, 2625439, 3099357, 3152811, 3108979, 3120165, 3245953, 3178109, 3211395, 3164477, 3119959, 3164462, 3036883, 3112692, 3218578, 3224847
Related CVE numbers	N/A

This patch resolves the issues listed in ESXi-7.0U3o-22348816-standard.

ESXi7.0U3so - 22348808

Name	ESXi
Version	ESXi7.0U3so - 22348808
Release Date	September 28, 2023
Category	Security
Affected Components	• ESXi Component - core ESXi VIBs • ESXi Install/Upgrade Component • ESXi Tools Component
PRs Fixed	3219441, 3239369, 3236018, 3232099, 3232034, 3222887, 3217141, 3213025, 3187868, 3186342, 3164962, 3089785, 3160789, 3098679, 3089785, 3256457, 3178522, 3178519
Related CVE numbers	N/A

This patch resolves the issues listed in ESXi-7.0U3so-22348808-standard.

Known Issues

vSAN Issues

PR 2962316: vSAN File Service does not support NFSv4 delegations

vSAN File Service does not support NFSv4 delegations in this release.

Workaround: None

PR 3235496: Applications on a vSAN cluster become intermittently unresponsive

If the advanced option `preferHT` is enabled on an AMD server in a vSAN cluster, the virtual CPUs of a virtual machine run on the same last level cache. When the virtual CPUs are all very busy and an NVMe thread to handle I/Os happens to run also on the same last level cache, the NVMe thread takes very long to complete, because it competes for CPU resources with the busy VMs. As a result, the I/O latency is very high and might lead to intermittent unresponsiveness of storage and applications on the vSAN cluster. In the backlog, you see errors such as `Lost access to volume <uuid> due to connectivity issues. Recovery attempt is in progress and outcome will be reported shortly.`

Workaround: Use the command `esxcli system settings advanced set -o /Misc/vmknvmeCwYield -I 0` to avoid competition between the NVMe completion queue and busy virtual CPUs.

Miscellaneous Issues

Windows or Citrix virtual machines with NVIDIA virtual GPU (vGPU) might intermittently fail with a blue diagnostics screen

After upgrading to ESXi 7.0 Update 3o, some Windows or Citrix vGPU VMs might fail due to insufficient file handles. Such VMs might need more than the default limit of 2048 handles.

Workaround: Apply the VM configuration setting `vmiop.maxFileHandles = 16384`.

Known Issues from Previous Releases

For a list of known issues from previous releases, see VMware ESXi 7.0 Update 3n Release Notes.

VMware ESXi 7.0 Update 3n Release Notes

This document contains the following sections

- Introduction
- What's New
- Earlier Releases of ESXi 7.0
- Patches Contained in This Release
- Patch Download and Installation
- Resolved Issues
- Known Issues from Previous Releases

Introduction

ESXi 7.0 Update 3n | JUL 06 2023 | Build 21930508 Check for additions and updates to these release notes.

IMPORTANT: If your source system contains hosts of versions between ESXi 7.0 Update 2 and Update 3c, and Intel drivers, before upgrading to ESXi 7.0 Update 3n, see the What's New section of the VMware vCenter Server 7.0 Update 3c Release Notes, because all content in the section is also applicable for vSphere 7.0 Update 3n. Also, see the related VMware knowledge base articles: 86447, 87258, and 87308.

What's New

- ESXi 7.0 Update 3n delivers bug fixes documented in the Resolved Issues section.

Earlier Releases of ESXi 7.0

New features, resolved, and known issues of ESXi are described in the release notes for each release. Release notes for earlier releases of ESXi 7.0 are:

- VMware ESXi 7.0, ESXi 7.0 Update 3m Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3l Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3k Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3j Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3i Release Notes

- VMware ESXi 7.0, ESXi 7.0 Update 3g Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3f Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2a Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2 Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1b Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1a Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1 Release Notes
- VMware ESXi 7.0, ESXi 7.0b Release Notes

For internationalization, compatibility, and open source components, see the VMware vSphere 7.0 Release Notes.

Patches Contained in This Release

This release of ESXi 7.0 Update 3n delivers the following patches:

Components

Component	Bulletin	Category	Severity
ESXi Component - core ESXi VIBs	ESXi_7.0.3-0.95.21930508	Bugfix	Critical
ESXi Install/Upgrade Component	esx-update_7.0.3-0.95.21930508	Bugfix	Critical

IMPORTANT:

- Starting with vSphere 7.0, VMware uses components for packaging VIBs along with bulletins. The **ESXi** and **esx-update** bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.

- When patching ESXi hosts by using VMware Update Manager from a version prior to ESXi 7.0 Update 2, it is strongly recommended to use the rollup bulletin in the patch baseline. If you cannot use the rollup bulletin, be sure to include *all* of the following packages in the patching baseline. If the following packages are not included in the baseline, the update operation fails:
  - VMware-vmkusb_0.1-1vmw.701.0.0.16850804 or higher
  - VMware-vmkata_0.1-1vmw.701.0.0.16850804 or higher
  - VMware-vmkfcoe_1.0.0.2-1vmw.701.0.0.16850804 or higher
  - VMware-NVMeoF-RDMA_1.0.1.2-1vmw.701.0.0.16850804 or higher

Rollup Bulletin

This rollup bulletin contains the latest VIBs with all the fixes after the initial release of ESXi 7.0.

Bulletin ID	Category	Severity
ESXi70U3n-21930508	Bugfix	Critical

Image Profiles

VMware patch and update releases contain general and critical image profiles. Application of the general release image profile applies to new bug fixes.

Image Profile Name
ESXi-7.0U3n-21930508-standard
ESXi-7.0U3n-21930508-no-tools

ESXi Image

Name and Version	Release Date	Category	Detail
ESXi70U3n-21930508	JUL 06 2023	Bugfix	Bugfix image

Patch Download and Installation

Log in to the Broadcom Support Portal to download this patch.

For download instructions for earlier releases, see Download Broadcom products and software.

In vSphere 7.x, the Update Manager plug-in, used for administering vSphere Update Manager, is replaced with the Lifecycle Manager plug-in. Administrative operations for vSphere Update Manager are still available under the Lifecycle Manager plug-in, along with new capabilities for vSphere Lifecycle Manager.

The typical way to apply patches to ESXi 7.x hosts is by using the vSphere Lifecycle Manager. For details, see About vSphere Lifecycle Manager and vSphere Lifecycle Manager Baselines and Images.

You can also update ESXi hosts without using the Lifecycle Manager plug-in, and use an image profile instead. To do this, you must manually download the patch offline bundle ZIP file.

For details, see Upgrading Hosts by Using ESXCLI Commands, and the VMware ESXi Upgrade guide.

Resolved Issues

ESXi_7.0.3-0.95.21930508

Patch Category	Bugfix

Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_bootbank_esx-base_7.0.3-0.95.21930508 • VMware_bootbank_trx_7.0.3-0.95.21930508 • VMware_bootbank_esx-dvfilter-generic-fastpath_7.0.3-0.95.21930508 • VMware_bootbank_vdfs_7.0.3-0.95.21930508 • VMware_bootbank_esxio-combiner_7.0.3-0.95.21930508 • VMware_bootbank_cpu-microcode_7.0.3-0.95.21930508 • VMware_bootbank_esx-xserver_7.0.3-0.95.21930508 • VMware_bootbank_vsan_7.0.3-0.95.21930508 • VMware_bootbank_native-misc-drivers_7.0.3-0.95.21930508 • VMware_bootbank_vsanhealth_7.0.3-0.95.21930508 • VMware_bootbank_gc_7.0.3-0.95.21930508 • VMware_bootbank_bmcal_7.0.3-0.95.21930508 • VMware_bootbank_crx_7.0.3-0.95.21930508
PRs Fixed	3192477, 3186367
CVE numbers	N/A

This patch updates the **esx-base** VIB. Due to their dependency with the **esx-base** VIB, the following VIBs are updated with build number and patch version changes, but deliver no fixes: **trx, esx-dvfilter-generic-fastpath, vdfs, esxio-combiner, cpu-microcode, esx-xserver, vsan, native-misc-drivers, vsanhealth, gc, bmcal** and **crx**. This patch resolves the following issues:

- **PR 3192477: Many LRO-capable PNICs do not aggregate packets from overlay traffic**
  Many physical networks adaptors (PNICs) that have the Hardware Large Receive Offload (LRO) capability might not aggregate packets from the Generic Network Virtualization Encapsulation (Geneve) overlay traffic.
  This issue is resolved in this release. The fix adds a software-based LRO functionality within the VMkernel that makes sure that if an LRO-capable PNIC does not aggregate packets from the Geneve overlay traffic, the VMkernel aggregates them instead. The change does not affect VLAN and VXLAN traffic.
- **PR 3186367: If virtual machines connected to an NSX logical switch stay on an ESXi host during a host reboot, such VMs might lose connectivity**
  If virtual machines connected to an NSX logical switch are not migrated and remain on an ESXi host during a host reboot, the VNICs of such VMs might lose connectivity.
  This issue is resolved in this release.

esx-update_7.0.3-0.95.21930508

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_bootbank_esx-update_7.0.3-0.95.21930508

	• VMware_bootbank_loadesx_7.0.3-0.95.21930508
PRs Fixed	N/A
CVE numbers	N/A

Due to their dependency with the **esx-base** VIB, the following VIBs are updated with build number and patch version changes, but deliver no fixes: **loadesx** and **esx-update**.

ESXi-7.0U3n-21930508-standard

Profile Name	ESXi-7.0U3n-21930508-standard
Build	For build information, see Patches Contained in this Release.

PRs Fixed	3192477, 3186367
Related CVE numbers	N/A

- **This patch resolves the following issues:**
  - Many physical networks adaptors (PNICs) that have the Hardware Large Receive Offload (LRO) capability might not aggregate packets from the Generic Network Virtualization Encapsulation (Geneve) overlay traffic.
  - If virtual machines connected to an NSX logical switch are not migrated and remain on an ESXi host during a host reboot, the VNICs of such VMs might lose connectivity.

ESXi70U3n-21930508

Name	ESXi
Version	ESXi70U3n-21930508
Release Date	July 06, 2023
Category	Bugfix
Affected Components	• ESXi Component - core ESXi VIBs • ESXi Install/Upgrade Component
PRs Fixed	3192477, 3186367
Related CVE numbers	N/A

Known Issues from Previous Releases

The earlier known issues are grouped as follows.

- vSAN Issues
- vSphere Cluster Services Issues
- Installation, Upgrade, and Migration Issues
- Security Features Issues
- Networking Issues
- Storage Issues

- vCenter Server and vSphere Client Issues
- Virtual Machine Management Issues
- vSphere HA and Fault Tolerance Issues
- vSphere Lifecycle Manager Issues
- Miscellaneous Issues
- vSphere Client Issues

vSAN Issues

If you change the preferred site in a VMware vSAN Stretched Cluster, some objects might incorrectly appear as compliant

If you change the preferred site in a stretched cluster, some objects might incorrectly appear as compliant, because their policy settings might not automatically change. For example, if you configure a virtual machine to keep data at the preferred site, when you change the preferred site, data might remain on the nonpreferred site.

Workaround: Before you change a preferred site, in Advanced Settings, lower the `ClomMaxCrawlCycleMinutes` setting to 15 min to make sure objects policies are updated. After the change, revert the `ClomMaxCrawlCycleMinutes` option to the earlier value.

vSphere Cluster Services Issues

You see compatibility issues in new vCLS VMs deployed in vSphere 7.0 Update 3 environment

The default name for new vCLS VMs deployed in vSphere 7.0 Update 3 environment uses the pattern vCLS-UUID. vCLS VMs created in earlier vCenter Server versions continue to use the pattern vCLS (n). Since the use of parenthesis () is not supported by many solutions that interoperate with vSphere, you might see compatibility issues.

Workaround: Reconfigure vCLS by using retreat mode after updating to vSphere 7.0 Update 3.

Installation, Upgrade, and Migration Issues

The vCenter Upgrade/Migration pre-checks fail with "Unexpected error 87"

The vCenter Server Upgrade/Migration pre-checks fail when the Security Token Service (STS) certificate does not contain a Subject Alternative Name (SAN) field. This situation occurs when you have replaced the vCenter 5.5 Single Sign-On certificate with a custom certificate that has no SAN field, and you attempt to upgrade to vCenter Server 7.0. The upgrade considers the STS certificate invalid and the pre-checks prevent the upgrade process from continuing.

Workaround: Replace the STS certificate with a valid certificate that contains a SAN field then proceed with the vCenter Server 7.0 Upgrade/Migration.

Problems upgrading to vSphere 7.0 with pre-existing CIM providers

After upgrade, previously installed 32-bit CIM providers stop working because ESXi requires 64-bit CIM providers. Customers may lose management API functions related to CIMPDK, NDDK (native DDK), HEXDK, VAIODK (IO filters), and see errors related to **uwglibc** dependency.

The syslog reports module missing, "32 bit shared libraries not loaded."

Workaround: There is no workaround. The fix is to download new 64-bit CIM providers from your vendor.

Installation of 7.0 Update 1 drivers on ESXi 7.0 hosts might fail

You cannot install drivers applicable to ESXi 7.0 Update 1 on hosts that run ESXi 7.0 or 7.0b.

The operation fails with an error, such as:

```
VMW_bootbank_qedrntv_3.40.4.0-12vmw.701.0.0.xxxxxxx requires vmkapi_2_7_0_0, but the
requirement cannot be satisfied within the ImageProfile. Please refer to the log file for
more details.
```

Workaround: Update the ESXi host to 7.0 Update 1. Retry the driver installation.

UEFI booting of ESXi hosts might stop with an error during an update to ESXi 7.0 Update 2 from an earlier version of ESXi 7.0

If you attempt to update your environment to 7.0 Update 2 from an earlier version of ESXi 7.0by using vSphere Lifecycle Manager patch baselines, UEFI booting of ESXi hosts might stop with an error such as:

```
Loading /boot.cfgFailed to load crypto64.efiFatal error: 15 (Not found)
```

Workaround: For more information, see VMware knowledge base articles 83063 and 83107 .

If legacy VIBs are in use on an ESXi host, vSphere Lifecycle Manager cannot extract a desired software specification to seed to a new cluster

With vCenter Server 7.0 Update 2, you can create a new cluster by importing the desired software specification from a single reference host. However, if legacy VIBs are in use on an ESXi host, vSphere Lifecycle Manager cannot extract in the vCenter Server instance where you create the cluster a reference software specification from such a host. In the `/var/log/lifecycle.log` , you see messages such as:

```
020-11-11T06:54:03Z lifecycle: 1000082644: HostSeeding:499
ERROR Extract depot failed: Checksum doesn't match. Calculated
5b404e28e83b1387841bb417da93c8c796ef2497c8af0f79583fd54e789d8826, expected:
0947542e30b794c721e21fb595f1851b247711d0619c55489a6a8cae6675e796 2020-11-11T06:54:04Z
lifecycle: 1000082644: imagemanagerctl:366 ERROR Extract depot failed.
2020-11-11T06:54:04Z lifecycle: 1000082644: imagemanagerctl:145 ERROR [VibChecksumError]
```

Workaround: Follow the steps described in VMware knowledge base article 83042.

You see a short burst of log messages in the syslog.log after every ESXi boot

After updating to ESXi 7.0 Update 2, you might see a short burst of log messages after every ESXi boot.

Such logs do not indicate any issue with ESXi and you can ignore these messages. For example:

```
2021-01-19T22:44:22Z watchdog-vaai-nasd: '/usr/lib/vmware/nfs/bin/vaai-nasd -f'
exited after 0 seconds (quick failure 127) 12021-01-19T22:44:22Z watchdog-vaai-
nasd: Executing '/usr/lib/vmware/nfs/bin/vaai-nasd -f'2021-01-19T22:44:22.990Z
aainasd[1000051135]: Log for VAAI-NAS Daemon for NFS version=1.0 build=build-00000
option=DEBUG2021-01-19T22:44:22.990Z vaainasd[1000051135]: DictionaryLoadFile: No entries
loaded by dictionary.2021-01-19T22:44:22.990Z vaainasd[1000051135]: DictionaryLoad: Cannot
open file "/usr/lib/vmware/config": No such file or directory.2021-01-19T22:44:22.990Z

vaainasd[1000051135]: DISKLIB-PLUGIN : Not loading plugin /usr/lib/vmware/nas_plugins/
lib64: Not a shared library.
```

Workaround: None

You see warning messages for missing VIBs in vSphere Quick Boot compatibility check reports

After you upgrade to ESXi 7.0 Update 2, if you check vSphere Quick Boot compatibility of your environment by using the `/usr/lib/vmware/loadesx/bin/loadESXCheckCompat.py` command, you might see some warning messages for missing VIBs in the shell. For example:

```
Cannot find VIB(s) ... in the given VIB collection.Ignoring missing reserved VIB(s) ...,
they are removed from reserved VIB IDs.
```

Such warnings do not indicate a compatibility issue.

Workaround: The missing VIB messages can be safely ignored and do not affect the reporting of vSphere Quick Boot compatibility. The final output line of the `loadESXCheckCompat` command unambiguously indicates if the host is compatible.

Auto bootstrapping a cluster that you manage with a vSphere Lifecycle Manager image fails with an error

If you attempt auto bootstrapping a cluster that you manage with a vSphere Lifecycle Manager image to perform a stateful install and overwrite the VMFS partitions, the operation fails with an error. In the support bundle, you see messages such as:

```
2021-02-11T19:37:43Z Host Profiles[265671 opID=MainThread]: ERROR:
EngineModule::ApplyHostConfig. Exception: [Errno 30] Read-only file system
```

Workaround: Follow vendor guidance to clean the VMFS partition in the target host and retry the operation. Alternatively, use an empty disk. For more information on the disk-partitioning utility on ESXi, see VMware knowledge base article 1036609.

Upgrades to ESXi 7.x from 6.5.x and 6.7.0 by using ESXCLI might fail due to a space limitation

Upgrades to ESXi 7.x from 6.5.x and 6.7.0 by using the `esxcli software profile update` or `esxcli software profile install` ESXCLI commands might fail, because the ESXi bootbank might be less than the size of the image profile. In the ESXi Shell or the PowerCLI shell, you see an error such as:

```
[InstallationError]
The pending transaction requires 244 MB free space, however the maximum supported size is 239 MB.
Please refer to the log file for more details.
```

The issue also occurs when you attempt an ESXi host upgrade by using the ESXCLI commands `esxcli software vib update` or `esxcli software vib install`.

Workaround: You can perform the upgrade in two steps, by using the `esxcli software profile update` command to update ESXi hosts to ESXi 6.7 Update 1 or later, and then update to 7.0 Update 1c. Alternatively, you can run an upgrade by using an ISO image and the vSphere Lifecycle Manager.

You cannot migrate linked clones across vCenter Servers

If you migrate a linked clone across vCenter Servers, operations such as power on and delete might fail for the source virtual machine with an `Invalid virtual machine state` error.

Workaround: Keep linked clones on the same vCenter Server as the source VM. Alternatively, promote the linked clone to full clone before migration.

Migration across vCenter Servers of virtual machines with many virtual disks and snapshot levels to a datastore on NVMe over TCP storage might fail

Migration across vCenter Servers of virtual machines with more than 180 virtual disks and 32 snapshot levels to a datastore on NVMe over TCP storage might fail. The ESXi host preemptively fails with an error such as `The migration has exceeded the maximum switchover time of 100 second(s).`

Workaround: None

A virtual machine with enabled Virtual Performance Monitoring Counters (VPMC) might fail to migrate between ESXi hosts

If you try to migrate a virtual machine with enabled VPMC by using vSphere vMotion, the operation might fail if the target host is using some of the counters to compute memory or performance statistics. The operation fails with an error such as `A performance counter used by the guest is not available on the host CPU.`

Workaround: Power off the virtual machine and use cold migration. For more information, see VMware knowledge base article 81191.

If a live VIB install, upgrade, or remove operation immediately precedes an interactive or scripted upgrade to ESXi 7.0 Update 3 by using the installer ISO, the upgrade fails

When a VIB install, upgrade, or remove operation immediately precedes an interactive or scripted upgrade to ESXi 7.0 Update 3 by using the installer ISO, the ConfigStore might not keep some configurations of the upgrade. As a result, ESXi hosts become inaccessible after the upgrade operation, although the upgrade seems successful. To prevent this issue, the ESXi 7.0 Update 3 installer adds a temporary check to block such scenarios. In the ESXi installer console, you see the following error message: `Live VIB installation, upgrade or removal may cause subsequent ESXi upgrade to fail when using the ISO installer.`

Workaround: Use an alternative upgrade method to avoid the issue, such as using ESXCLI or the vSphere Lifecycle Manager.

Smart Card and RSA SecurID authentication might stop working after upgrading to vCenter Server 7.0

If you have configured vCenter Server for either Smart Card or RSA SecurID authentication, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057 before starting the vSphere 7.0 upgrade process. If you do not perform the workaround as described in the KB, you might see the following error messages and Smart Card or RSA SecurID authentication does not work.

"Smart card authentication may stop working. Smart card settings may not be preserved, and smart card authentication may stop working."

or

"RSA SecurID authentication may stop working. RSA SecurID settings may not be preserved, and RSA SecurID authentication may stop working."

Workaround: Before upgrading to vSphere 7.0, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057.

The vlanid property in custom installation scripts might not work

If you use a custom installation script that sets the `vlanid` property to specify a desired VLAN, the property might not take effect on newly installed ESXi hosts. The issue occurs only when a physical NIC is already connected to DHCP when the installation starts. The `vlanid` property works properly when you use a newly connected NIC.

Workaround: Manually set the VLAN from the Direct Console User Interface after you boot the ESXi host. Alternatively, disable the physical NIC and then boot the host.

HPE servers with Trusted Platform Module (TPM) boot, but remote attestation fails

Some HPE servers do not have enough event log space to properly finish TPM remote attestation. As a result, the VMkernel boots, but remote attestation fails due to the truncated log.

Workaround: None.

Upgrading a vCenter Server with an external Platform Services Controller from 6.7u3 to 7.0 fails with VMAFD error

When you upgrade a vCenter Server deployment using an external Platform Services Controller, you converge the Platform Services Controller into a vCenter Server appliance. If the upgrade fails with the error `install.vmafd.vmdir_vdcpromo_error_21`, the VMAFD firstboot process has failed. The VMAFD firstboot process copies the VMware Directory Service Database (data.mdb) from the source Platform Services Controller and replication partner vCenter Server appliance.

Workaround: Disable TCP Segmentation Offload (TSO) and Generic Segmentation Offload (GSO) on the Ethernet adapter of the source Platform Services Controller or replication partner vCenter Server appliance before upgrading a vCenter Server with an external Platform Services Controller. See Knowledge Base article: https://kb.vmware.com/s/article/74678

Smart card and RSA SecurID settings may not be preserved during vCenter Server upgrade

Authentication using RSA SecurID will not work after upgrading to vCenter Server 7.0. An error message will alert you to this issue when attempting to login using your RSA SecurID login.

Workaround: Reconfigure the smart card or RSA SecureID.

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with network error message

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with the error message `IP already exists in the network`. This prevents the migration process from configuring the network parameters on the new vCenter Server appliance. For more information, examine the log file: `/var/log/vmware/upgrade/UpgradeRunner.log`

Workaround:

1. Verify that all Windows Updates have been completed on the source vCenter Server for Windows instance, or disable automatic Windows Updates until after the migration finishes.
2. Retry the migration of vCenter Server for Windows to vCenter Server appliance 7.0.

When you configure the number of virtual functions for an SR-IOV device by using the max_vfs module parameter, the changes might not take effect

In vSphere 7.0, you can configure the number of virtual functions for an SR-IOV device by using the Virtual Infrastructure Management (VIM) API, for example, through the vSphere Client. The task does not require reboot of the ESXi host. After you use the VIM API configuration, if you try to configure the number of SR-IOV virtual functions by using the `max_vfs` module parameter, the changes might not take effect because they are overridden by the VIM API configuration.

Workaround: None. To configure the number of virtual functions for an SR-IOV device, use the same method every time. Use the VIM API or use the `max_vfs` module parameter and reboot the ESXi host.

Upgraded vCenter Server appliance instance does not retain all the secondary networks (NICs) from the source instance

During a major upgrade, if the source instance of the vCenter Server appliance is configured with multiple secondary networks other than the VCHA NIC, the target vCenter Server instance will not retain secondary networks other than the VCHA NIC. If the source instance is configured with multiple NICs that are part of VDS port groups, the NIC configuration will not be preserved during the upgrade. Configurations for vCenter Server appliance instances that are part of the standard port group will be preserved.

Workaround: None. Manually configure the secondary network in the target vCenter Server appliance instance.

After upgrading or migrating a vCenter Server with an external Platform Services Controller, users authenticating using Active Directory lose access to the newly upgraded vCenter Server instance

After upgrading or migrating a vCenter Server with an external Platform Services Controller, if the newly upgraded vCenter Server is not joined to an Active Directory domain, users authenticating using Active Directory will lose access to the vCenter Server instance.

Workaround: Verify that the new vCenter Server instance has been joined to an Active Directory domain. See Knowledge Base article: https://kb.vmware.com/s/article/2118543

Migrating a vCenter Server for Windows with an external Platform Services Controller using an Oracle database fails

If there are non-ASCII strings in the Oracle events and tasks table the migration can fail when exporting events and tasks data. The following error message is provided: UnicodeDecodeError

Workaround: None.

After an ESXi host upgrade, a Host Profile compliance check shows non-compliant status while host remediation tasks fail

The non-compliant status indicates an inconsistency between the profile and the host.

This inconsistency might occur because ESXi 7.0 does not allow duplicate claim rules, but the profile you use contains duplicate rules. For example, if you attempt to use the Host Profile that you extracted from the host before upgrading ESXi 6.5 or ESXi 6.7 to version 7.0 and the Host Profile contains any duplicate claim rules of system default rules, you might experience the problems.

Workaround:

1. Remove any duplicate claim rules of the system default rules from the Host Profile document.
2. Check the compliance status.
3. Remediate the host.
4. If the previous steps do not help, reboot the host.

Error message displays in the vCenter Server Management Interface

After installing or upgrading to vCenter Server 7.0, when you navigate to the Update panel within the vCenter Server Management Interface, the error message "Check the URL and try again" displays. The error message does not prevent you from using the functions within the Update panel, and you can view, stage, and install any available updates.

Workaround: None.

Security Features Issues

Turn off the Service Location Protocol service in ESXi, slpd, to prevent potential security vulnerabilities

Some services in ESXi that run on top of the host operating system, including slpd, the CIM object broker, sfcbd, and the related openwsmand service, have proven security vulnerabilities. VMware has addressed all known vulnerabilities in VMSA-2019-0022 and VMSA-2020-0023, and the fixes are part of the vSphere 7.0 Update 2 release. While sfcbd and openwsmand are disabled by default in ESXi, slpd is enabled by default and you must turn it off, if not necessary, to prevent exposure to a future vulnerability after an upgrade.

Workaround: To turn off the slpd service, run the following PowerCLI commands:

```
$ Get-VMHost | Get-VmHostService | Where-Object {$_.key -eq "slpd"} | Set-VMHostService -policy "off"$ Get-VMHost | Get-VmHostService | Where-Object {$_.key -eq "slpd"} | Stop-VMHostService -Confirm:$false
```

Alternatively, you can use the command `chkconfig slpd off && /etc/init.d/slpd stop`.

The openwsmand service is not on the ESXi services list and you can check the service state by using the following PowerCLI commands:

```
$esx=(Get-EsxCli -vmhost xx.xx.xx.xx -v2)$esx.system.process.list.invoke() | where CommandLine -like '*openwsman*' | select commandline
```

In the ESXi services list, the sfcbd service appears as sfcbd-watchdog.

For more information, see VMware knowledge base articles 76372 and 1025757.

Encrypted virtual machine fails to power on when HA-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled HA on the Trusted Cluster and one or more hosts in the cluster fails attestation, an encrypted virtual machine cannot power on.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Encrypted virtual machine fails to power on when DRS-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled DRS on the Trusted Cluster and one or more hosts in the cluster fails attestation, DRS might try to power on an encrypted virtual machine on an unattested host in the cluster. This operation puts the virtual machine in a locked state.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Migrating or cloning encrypted virtual machines across vCenter Server instances fails when attempting to do so using the vSphere Client

If you try to migrate or clone an encrypted virtual machine across vCenter Server instances using the vSphere Client, the operation fails with the following error message: "The operation is not allowed in the current state."

Workaround: You must use the vSphere APIs to migrate or clone encrypted virtual machines across vCenter Server instances.

Networking Issues

Reduced throughput in networking performance on Intel 82599/X540/X550 NICs

The new queue-pair feature added to ixgben driver to improve networking performance on Intel 82599EB/X540/X550 series NICs might reduce throughput under some workloads in vSphere 7.0 as compared to vSphere 6.7.

Workaround: To achieve the same networking performance as vSphere 6.7, you can disable the queue-pair with a module parameter. To disable the queue-pair, run the command:

```
# esxcli system module parameters set -p "QPair=0,0,0,0..." -m ixgben
```

After running the command, reboot.

One or more I/O devices do not generate interrupts when the AMD IOMMU is in use

If the I/O devices on your ESXi host provide more than a total of 512 distinct interrupt sources, some sources are erroneously assigned an interrupt-remapping table entry (IRTE) index in the AMD IOMMU that is greater than the maximum value. Interrupts from such a source are lost, so the corresponding I/O device behaves as if interrupts are disabled.

Workaround: Use the ESXCLI command `esxcli system settings kernel set -s iovDisableIR -v true` to disable the AMD IOMMU interrupt remapper. Reboot the ESXi host so that the command takes effect.

When you set auto-negotiation on a network adapter, the device might fail

In some environments, if you set link speed to auto-negotiation for network adapters by using the command `esxcli network nic set -a -n vmmicx`, the devices might fail and reboot does not recover connectivity. The issue is specific to a combination of some Intel X710/X722 network adapters, a SFP+ module and a physical switch, where auto-negotiate speed/duplex scenario is not supported.

Workaround: Make sure you use an Intel-branded SFP+ module. Alternatively, use a Direct Attach Copper (DAC) cable.

Solarflare x2542 and x2541 network adapters configured in 1x100G port mode achieve throughput of up to 70Gbps in a vSphere environment

vSphere 7.0 Update 2 supports Solarflare x2542 and x2541 network adapters configured in 1x100G port mode. However, you might see a hardware limitation in the devices that causes the actual throughput to be up to some 70Gbps in a vSphere environment.

Workaround: None

VLAN traffic might fail after a NIC reset

A NIC with PCI device ID 8086:1537 might stop to send and receive VLAN tagged packets after a reset, for example, with a command `vsish -e set /net/pNics/vmnic0/reset 1`.

Workaround: Avoid resetting the NIC. If you already face the issue, use the following commands to restore the VLAN capability, for example at vmnic0:

```
# esxcli network nic software set --tagging=1 -n vmnic0# esxcli network nic software set --tagging=0 -n vmnic0
```

Any change in the NetQueue balancer settings causes NetQueue to be disabled after an ESXi host reboot

Any change in the NetQueue balancer settings by using the command `esxcli/localcli network nic queue loadbalancer set -n <nicname> --<lb_setting>` causes NetQueue, which is enabled by default, to be disabled after an ESXi host reboot.

Workaround: After a change in the NetQueue balancer settings and host reboot, use the command `configstorecli config current get -c esx -g network -k nics` to retrieve ConfigStore data to verify whether the `/esx/network/nics/net_queue/load_balancer/enable` is working as expected.

After you run the command, you see output similar to:

```
{"mac": "02:00:0e:6d:14:3e","name": "vmnic1","net_queue": { "load_balancer": { "dynamic_pool": true, "enable": true }},"virtual_mac": "00:50:56:5a:21:11"}
```

If the output is not as expected, for example `"load_balancer": "enable": false"`, run the following command:

```
esxcli/localcli network nic queue loadbalancer state set -n <nicname> -e true
```

Paravirtual RDMA (PVRDMA) network adapters do not support NSX networking policies

If you configure an NSX distributed virtual port for use in PVRDMA traffic, the RDMA protocol traffic over the PVRDMA network adapters does not comply with the NSX network policies.

Workaround: Do not configure NSX distributed virtual ports for use in PVRDMA traffic.

Rollback from converged vSphere Distributed Switch (VDS) to NSX-T VDS is not supported in vSphere 7.0 Update 3

Rollback from converged VDS that supports both vSphere 7 traffic and NSX-T 3 traffic on the same VDS to one N-VDS for NSX-T traffic is not supported in vSphere 7.0 Update 3.

Workaround: None

If you do not set the nmlx5 network driver module parameter, network connectivity or ESXi hosts might fail

If you do not set the `supported_num_ports` module parameter for the `nmlx5_core` driver on an ESXi host with multiple network adapters of versions Mellanox ConnectX-4, Mellanox ConnectX-5 and Mellanox ConnectX-6, the driver might not allocate sufficient memory for operating all the NIC ports for the host. As a result, you might experience network loss or ESXi host failure with purple diagnostic screen, or both.

Workaround: Set the `supported_num_ports` module parameter value in the `nmlx5_core` network driver equal to the total number of Mellanox ConnectX-4, Mellanox ConnectX-5 and Mellanox ConnectX-6 network adapter ports on the ESXi host.

High throughput virtual machines may experience degradation in network performance when Network I/O Control (NetIOC) is enabled

Virtual machines requiring high network throughput can experience throughput degradation when upgrading from vSphere 6.7 to vSphere 7.0 with NetIOC enabled.

Workaround: Adjust the `ethernetx.ctxPerDev` setting to enable multiple worlds.

IPv6 traffic fails to pass through VMkernel ports using IPsec

When you migrate VMkernel ports from one port group to another, IPv6 traffic does not pass through VMkernel ports using IPsec.

Workaround: Remove the IPsec security association (SA) from the affected server, and then reapply the SA. To learn how to set and remove an IPsec SA, see the *vSphere Security* documentation.

Higher ESX network performance with a portion of CPU usage increase

ESX network performance may increase with a portion of CPU usage.

Workaround: Remove and add the network interface with only 1 rx dispatch queue. For example:

```
esxcli network ip interface remove --interface-name=vmk1
```

```
esxcli network ip interface add --interface-name=vmk1 --num-rxqueue=1
```

VM might lose Ethernet traffic after hot-add, hot-remove or storage vMotion

A VM might stop receiving Ethernet traffic after a hot-add, hot-remove or storage vMotion. This issue affects VMs where the uplink of the VNIC has SR-IOV enabled. PVRDMA virtual NIC exhibits this issue when the uplink of the virtual network is a Mellanox RDMA capable NIC and RDMA namespaces are configured.

Workaround: You can hot-remove and hot-add the affected Ethernet NICs of the VM to restore traffic. On Linux guest operating systems, restarting the network might also resolve the issue. If these workarounds have no effect, you can reboot the VM to restore network connectivity.

Change of IP address for a VCSA deployed with static IP address requires that you create the DNS records in advance

With the introduction of the DDNS, the DNS record update only works for VCSA deployed with DHCP configured networking. While changing the IP address of the vCenter server via VAMI, the following error is displayed:

The specified IP address does not resolve to the specified hostname.

Workaround: There are two possible workarounds.

1. Create an additional DNS entry with the same FQDN and desired IP address. Log in to the VAMI and follow the steps to change the IP address.
2. Log in to the VCSA using ssh. Execute the following script:
   `./opt/vmware/share/vami/vami_config_net`

Use option 6 to change the IP adddress of eth0. Once changed, execute the following script:
`./opt/likewise/bin/lw-update-dns`
Restart all the services on the VCSA to update the IP information on the DNS server.

It may take several seconds for the NSX Distributed Virtual Port Group (NSX DVPG) to be removed after deleting the corresponding logical switch in NSX Manager.

As the number of logical switches increases, it may take more time for the NSX DVPG in vCenter Server to be removed after deleting the corresponding logical switch in NSX Manager. In an environment with 12000 logical switches, it takes approximately 10 seconds for an NSX DVPG to be deleted from vCenter Server.

Workaround: None.

Hostd runs out of memory and fails if a large number of NSX Distributed Virtual port groups are created.

In vSphere 7.0, NSX Distributed Virtual port groups consume significantly larger amounts of memory than opaque networks. For this reason, NSX Distributed Virtual port groups can not support the same scale as an opaque network given the same amount of memory.

Workaround:To support the use of NSX Distributed Virtual port groups, increase the amount of memory in your ESXi hosts. If you verify that your system has adequate memory to support your VMs, you can directly increase the memory of `hostd` using the following command.

```
localcli --plugin-dir /usr/lib/vmware/esxcli/int/ sched group setmemconfig --group-path
host/vim/vmvisor/hostd --units mb --min 2048 --max 2048
```

Note that this will cause `hostd` to use memory normally reserved for your environment's VMs. This may have the affect of reducing the number of VMs your ESXi host can support.

DRS may incorrectly launch vMotion if the network reservation is configured on a VM

If the network reservation is configured on a VM, it is expected that DRS only migrates the VM to a host that meets the specified requirements. In a cluster with NSX transport nodes, if some of the transport nodes join the transport zone by NSX-T Virtual Distributed Switch (N-VDS), and others by vSphere Distributed Switch (VDS) 7.0, DRS may incorrectly launch vMotion. You might encounter this issue when:

- The VM connects to an NSX logical switch configured with a network reservation.
- Some transport nodes join transport zone using N-VDS, and others by VDS 7.0, or, transport nodes join the transport zone through different VDS 7.0 instances.

Workaround: Make all transport nodes join the transport zone by N-VDS or the same VDS 7.0 instance.

When adding a VMkernel NIC (vmknic) to an NSX portgroup, vCenter Server reports the error "Connecting VMKernel adapter to a NSX Portgroup on a Stateless host is not a supported operation. Please use Distributed Port Group instead."

- For stateless ESXi on Distributed Virtual Switch (VDS), the vmknic on a NSX port group is blocked. You must instead use a Distributed Port Group.
- For stateful ESXi on VDS, vmknic on NSX port group is supported, but vSAN may have an issue if it is using vmknic on a NSX port group.

Workaround: Use a Distributed Port Group on the same VDS.

Enabling SRIOV from vCenter for QLogic 4x10GE QL41164HFCU CNA might fail

If you navigate to the **Edit Settings** dialog for physical network adapters and attempt to enable SR-IOV, the operation might fail when using QLogic 4x10GE QL41164HFCU CNA. Attempting to enable SR-IOV might lead to a network outage of the ESXi host.

Workaround: Use the following command on the ESXi host to enable SRIOV:

```
esxcfg-module
```

vCenter Server fails if the hosts in a cluster using Distributed Resource Scheduler (DRS) join NSX-T networking by a different Virtual Distributed Switch (VDS) or combination of NSX-T Virtual Distributed Switch (NVDS) and VDS

In vSphere 7.0, when using NSX-T networking on vSphere VDS with a DRS cluster, if the hosts do not join the NSX transport zone by the same VDS or NVDS, it can cause vCenter Server to fail.

Workaround: Have hosts in a DRS cluster join the NSX transport zone using the same VDS or NVDS.

Storage Issues

VMFS datastores are not mounted automatically after disk hot remove and hot insert on HPE Gen10 servers with SmartPQI controllers

When SATA disks on HPE Gen10 servers with SmartPQI controllers without expanders are hot removed and hot inserted back to a different disk bay of the same machine, or when multiple disks are hot removed and hot inserted back in a different order, sometimes a new local name is assigned to the disk. The VMFS datastore on that disk appears as a snapshot and will not be mounted back automatically because the device name has changed.

Workaround: None. SmartPQI controller does not support unordered hot remove and hot insert operations.

VOMA check on NVMe based VMFS datastores fails with error

VOMA check is not supported for NVMe based VMFS datastores and will fail with the error:

```
ERROR: Failed to reserve device. Function not implemented
```

Example:

```
# voma -m vmfs -f check -d /vmfs/devices/disks/: <partition#>
Running VMFS Checker version 2.1 in check mode
Initializing LVM metadata, Basic Checks will be done

Checking for filesystem activity
Performing filesystem liveness check..|Scanning for VMFS-6 host activity (4096 bytes/HB, 1024 HBs).
ERROR: Failed to reserve device. Function not implemented
Aborting VMFS volume check
VOMA failed to check device : General Error
```

Workaround: None. If you need to analyse VMFS metadata, collect it using the `-l` option, and pass to VMware customer support. The command for collecting the dump is:

```
voma -l -f dump -d /vmfs/devices/disks/:<partition#>
```

Using the VM reconfigure API to attach an encrypted First Class Disk to an encrypted virtual machine might fail with error

If an FCD and a VM are encrypted with different crypto keys, your attempts to attach the encrypted FCD to the encrypted VM using the `VM reconfigure API` might fail with the error message:

```
Cannot decrypt disk because key or password is incorrect.
```

Workaround: Use the `attachDisk API` rather than the `VM reconfigure API` to attach an encrypted FCD to an encrypted VM.

ESXi host might get in non responding state if a non-head extent of its spanned VMFS datastore enters the Permanent Device Loss (PDL) state

This problem does not occur when a non-head extent of the spanned VMFS datastore fails along with the head extent. In this case, the entire datastore becomes inaccessible and no longer allows I/Os.

In contrast, when only a non-head extent fails, but the head extent remains accessible, the datastore heartbeat appears to be normal. And the I/Os between the host and the datastore continue. However, any I/Os that depend on the failed non-head extent start failing as well. Other I/O transactions might accumulate while waiting for the failing I/Os to resolve, and cause the host to enter the non responding state.

Workaround: Fix the PDL condition of the non-head extent to resolve this issue.

Virtual NVMe Controller is the default disk controller for Windows 10 guest operating systems

The Virtual NVMe Controller is the default disk controller for the following guest operating systems when using Hardware Version 15 or later:

Windows 10

Windows Server 2016

Windows Server 2019

Some features might not be available when using a Virtual NVMe Controller. For more information, see https://kb.vmware.com/s/article/2147714

Note: Some clients use the previous default of LSI Logic SAS. This includes ESXi host client and PowerCLI.

Workaround: If you need features not available on Virtual NVMe, switch to VMware Paravirtual SCSI (PVSCSI) or LSI Logic SAS. For information on using VMware Paravirtual SCSI (PVSCSI), see https://kb.vmware.com/s/article/1010398

After an ESXi host upgrade to vSphere 7.0, presence of duplicate core claim rules might cause unexpected behavior

Claim rules determine which multipathing plugin, such as NMP, HPP, and so on, owns paths to a particular storage device. ESXi 7.0 does not support duplicate claim rules. However, the ESXi 7.0 host does not alert you if you add duplicate rules to the existing claim rules inherited through an upgrade from a legacy release. As a result of using duplicate rules, storage devices might be claimed by unintended plugins, which can cause unexpected outcome.

Workaround: Do not use duplicate core claim rules. Before adding a new claim rule, delete any existing matching claim rule.

A CNS query with the compliance status filter set might take unusually long time to complete

The CNS QueryVolume API enables you to obtain information about the CNS volumes, such as volume health and compliance status. When you check the compliance status of individual volumes, the results are obtained quickly. However, when you invoke the CNS QueryVolume API to check the compliance status of multiple volumes, several tens or hundreds, the query might perform slowly.

Workaround: Avoid using bulk queries. When you need to get compliance status, query one volume at a time or limit the number of volumes in the query API to 20 or fewer. While using the query, avoid running other CNS operations to get the best performance.

A VMFS datastore backed by an NVMe over Fabrics namespace or device might become permanently inaccessible after recovering from an APD or PDL failure

If a VMFS datastore on an ESXi host is backed by an NVMe over Fabrics namespace or device, in case of an all paths down (APD) or permanent device loss (PDL) failure, the datastore might be inaccessible even after recovery. You cannot access the datastore from either the ESXi host or the vCenter Server system.

Workaround: To recover from this state, perform a rescan on a host or cluster level. For more information, see Perform Storage Rescan.

Deleted CNS volumes might temporarily appear as existing in the CNS UI

After you delete an FCD disk that backs a CNS volume, the volume might still show up as existing in the CNS UI. However, your attempts to delete the volume fail. You might see an error message similar to the following:

```
The object or item referred to could not be found.
```

Workaround: The next full synchronization will resolve the inconsistency and correctly update the CNS UI.

Attempts to attach multiple CNS volumes to the same pod might occasionally fail with an error

When you attach multiple volumes to the same pod simultaneously, the attach operation might occasionally choose the same controller slot. As a result, only one of the operations succeeds, while other volume mounts fail.

Workaround: After Kubernetes retries the failed operation, the operation succeeds if a controller slot is available on the node VM.

Under certain circumstances, while a CNS operation fails, the task status appears as successful in the vSphere Client

This might occur when, for example, you use an incompliant storage policy to create a CNS volume. The operation fails, while the vSphere Client shows the task status as successful.

Workaround: The successful task status in the vSphere Client does not guarantee that the CNS operation succeeded. To make sure the operation succeeded, verify its results.

Unsuccessful delete operation for a CNS persistent volume might leave the volume undeleted on the vSphere datastore

This issue might occur when the CNS Delete API attempts to delete a persistent volume that is still attached to a pod. For example, when you delete the Kubernetes namespace where the pod runs. As a result, the volume gets cleared from CNS and the CNS query operation does not return the volume. However, the volume continues to reside on the datastore and cannot be deleted through the repeated CNS Delete API operations.

Workaround: None.

vCenter Server and vSphere Client Issues

Vendor providers go offline after a PNID change

When you change the vCenter IP address (PNID change), the registered vendor providers go offline.

Workaround: Re-register the vendor providers.

Cross vCenter migration of a virtual machine fails with an error

When you use cross vCenter vMotion to move a VM's storage and host to a different vCenter server instance, you might receive the error `The operation is not allowed in the current state.`

This error appears in the UI wizard after the Host Selection step and before the Datastore Selection step, in cases where the VM has an assigned storage policy containing host-based rules such as encryption or any other IO filter rule.

Workaround: Assign the VM and its disks to a storage policy without host-based rules. You might need to decrypt the VM if the source VM is encrypted. Then retry the cross vCenter vMotion action.

Storage Sensors information in Hardware Health tab shows incorrect values on vCenter UI, host UI, and MOB

When you navigate to **Host > Monitor > Hardware Health > Storage Sensors** on vCenter UI, the storage information displays either incorrect or unknown values. The same issue is observed on the host UI and the MOB path `"runtime.hardwareStatusInfo.storageStatusInfo"` as well.

Workaround: None.

vSphere UI host advanced settings shows the current product locker location as empty with an empty default

vSphere UI host advanced settings shows the current product locker location as empty with an empty default. This is inconsistent as the actual product location `symlink` is created and valid. This causes confusion to the user. The default cannot be corrected from UI.

Workaround: User can use the esxcli command on the host to correct the current product locker location default as below.

1. Remove the existing Product Locker Location setting with: "`esxcli system settings advanced remove -o ProductLockerLocation`"

2. Re-add the Product Locker Location setting with the appropriate default:

2.a. If the ESXi is a full installation, the default value is "`/locker/packages/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/locker/packages/vmtoolsRepo`"

2.b. If the ESXi is a PXEboot configuration such as autodeploy, the default value is: "`/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/vmtoolsRepo`"

Run the following command to automatically figure out the location: `export PRODUCT_LOCKER_DEFAULT=`readlink /productLocker``

Add the setting: `esxcli system settings advanced add -d "Path to VMware Tools repository" -o ProductLockerLocation -t string -s $PRODUCT_LOCKER_DEFAULT`

You can combine all the above steps in step 2 by issuing the single command:

```
esxcli system settings advanced add -d "Path to VMware Tools repository" -o
ProductLockerLocation -t string -s `readlink /productLocker`
```

Linked Software-Defined Data Center (SDDC) vCenter Server instances appear in the on-premises vSphere Client if a vCenter Cloud Gateway is linked to the SDDC.

When a vCenter Cloud Gateway is deployed in the same environment as an on-premises vCenter Server, and linked to an SDDC, the SDDC vCenter Server will appear in the on-premises vSphere Client. This is unexpected behavior and the linked SDDC vCenter Server should be ignored. All operations involving the linked SDDC vCenter Server should be performed on the vSphere Client running within the vCenter Cloud Gateway.

Workaround: None.

Virtual Machine Management Issues

UEFI HTTP booting of virtual machines on ESXi hosts of version earlier than 7.0 Update 2 fails

UEFI HTTP booting of virtual machines is supported only on hosts of version ESXi 7.0 Update 2 and later and VMs with HW version 19 or later.

Workaround: Use UEFI HTTP booting only in virtual machines with HW version 19 or later. Using HW version 19 ensures the virtual machines are placed only on hosts with ESXi version 7.0 Update 2 or later.

Virtual machine snapshot operations fail in vSphere Virtual Volumes datastores on Purity version 5.3.10

Virtual machine snapshot operations fail in vSphere Virtual Volumes datastores on Purity version 5.3.10 with an error such as `An error occurred while saving the snapshot: The VVol target encountered a vendor specific error`. The issue is specific for Purity version 5.3.10.

Workaround: Upgrade to Purity version 6.1.7 or follow vendor recommendations.

The postcustomization section of the customization script runs before the guest customization

When you run the guest customization script for a Linux guest operating system, the `precustomization` section of the customization script that is defined in the customization specification runs before the guest customization and the `postcustomization` section runs after that. If you enable Cloud-Init in the guest operating system of a virtual machine, the `postcustomization` section runs before the customization due to a known issue in Cloud-Init.

Workaround: Disable Cloud-Init and use the standard guest customization.

Group migration operations in vSphere vMotion, Storage vMotion, and vMotion without shared storage fail with error

When you perform group migration operations on VMs with multiple disks and multi-level snapshots, the operations might fail with the error `com.vmware.vc.GenericVmConfigFault Failed waiting for data. Error 195887167. Connection closed by remote host, possibly due to timeout.`

Workaround: Retry the migration operation on the failed VMs one at a time.

Deploying an OVF or OVA template from a URL fails with a 403 Forbidden error

The URLs that contain an HTTP query parameter are not supported. For example, `http://webaddress.com?file=abc.ovf` or the Amazon pre-signed S3 URLs.

Workaround: Download the files and deploy them from your local file system.

The third level of nested objects in a virtual machine folder is not visible

Perform the following steps:

1. Navigate to a data center and create a virtual machine folder.
2. In the virtual machine folder, create a nested virtual machine folder.
3. In the second folder, create another nested virtual machine, virtual machine folder, vApp, or VM Template.

As a result, from the VMs and Templates inventory tree you cannot see the objects in the third nested folder.

Workaround: To see the objects in the third nested folder, navigate to the second nested folder and select the VMs tab.

vSphere HA and Fault Tolerance Issues

VMs in a cluster might be orphaned after recovering from storage inaccessibility such as a cluster wide APD

Some VMs might be in orphaned state after cluster wide APD recovers, even if HA and VMCP are enabled on the cluster.

This issue might be encountered when the following conditions occur simultaneously:

- All hosts in the cluster experience APD and do not recover until VMCP timeout is reached.
- HA primary initiates failover due to APD on a host.
- Power on API during HA failover fails due to one of the following:
  - APD across the same host
  - Cascading APD across the entire cluster
  - Storage issues
  - Resource unavailability
- FDM unregistration and VCs steal VM logic might initiate during a window where FDM has not unregistered the failed VM and VC's host synchronization responds that multiple hosts are reporting the same VM. Both FDM and VC unregister the different registered copies of the same VM from different hosts, causing the VM to be orphaned.

Workaround: You must unregister and reregister the orphaned VMs manually within the cluster after the APD recovers.

If you do not manually reregister the orphaned VMs, HA attempts failover of the orphaned VMs, but it might take between 5 to 10 hours depending on when APD recovers.

The overall functionality of the cluster is not affected in these cases and HA will continue to protect the VMs. This is an anomaly in what gets displayed on VC for the duration of the problem.

vSphere Lifecycle Manager Issues

You cannot enable NSX-T on a cluster that is already enabled for managing image setup and updates on all hosts collectively

NSX-T is not compatible with the vSphere Lifecycle Manager functionality for image management. When you enable a cluster for image setup and updates on all hosts in the cluster collectively, you cannot enable NSX-T on that cluster. However, you can deploy NSX Edges to this cluster.

Workaround: Move the hosts to a new cluster that you can manage with baselines and enable NSX-T on that new cluster.

vSphere Lifecycle Manager and vSAN File Services cannot be simultaneously enabled on a vSAN cluster in vSphere 7.0 release

If vSphere Lifecycle Manager is enabled on a cluster, vSAN File Services cannot be enabled on the same cluster and vice versa. In order to enable vSphere Lifecycle Manager on a cluster, which has VSAN File Services enabled already, first disable vSAN File Services and retry the operation. Please note that if you transition to a cluster that is managed by a single image, vSphere Lifecycle Manager cannot be disabled on that cluster.

Workaround: None.

When a hardware support manager is unavailable, vSphere High Availability (HA) functionality is impacted

If hardware support manager is unavailable for a cluster that you manage with a single image, where a firmware and drivers addon is selected and vSphere HA is enabled, the vSphere HA functionality is impacted. You may experience the following errors.

- Configuring vSphere HA on a cluster fails.
- Cannot complete the configuration of the vSphere HA agent on a host: `Applying HA VIBs on the cluster encountered a failure.`
- Remediating vSphere HA fails: `A general system error occurred: Failed to get Effective Component map.`
- Disabling vSphere HA fails: Delete Solution task failed. `A general system error occurred: Cannot find hardware support package from depot or hardware support manager.`

Workaround:

- If the hardware support manager is temporarily unavailable, perform the following steps.

1. Reconnect the hardware support manager to vCenter Server.
2. Select a cluster from the Hosts and Cluster menu.
3. Select the Configure tab.
4. Under Services, click vSphere Availability.
5. Re-enable vSphere HA.

- If the hardware support manager is permanently unavailable, perform the following steps.

1. Remove the hardware support manager and the hardware support package from the image specification
2. Re-enable vSphere HA.
3. Select a cluster from the Hosts and Cluster menu.

4. Select the Updates tab.
5. Click Edit .
6. Remove the firmware and drivers addon and click Save.
7. Select the Configure tab.
8. Under Services, click vSphere Availability.
9. Re-enable vSphere HA.

I/OFilter is not removed from a cluster after a remediation process in vSphere Lifecycle Manager

Removing I/OFilter from a cluster by remediating the cluster in vSphere Lifecycle Manager, fails with the following error message: `iofilter XXX already exists` . The iofilter remains listed as installed.

Workaround:

1. Call IOFilter API `UninstallIoFilter_Task` from the vCenter Server managed object (IoFilterManager).
2. Remediate the cluster in vSphere Lifecycle Manager.
3. Call IOFilter API `ResolveInstallationErrorsOnCluster_Task` from the vCenter Server managed object (IoFilterManager) to update the database.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, adding hosts causes a vSphere HA error state

Adding one or multiple ESXi hosts during a remediation process of a vSphere HA enabled cluster, results in the following error message: `Applying HA VIBs on the cluster encountered a failure.`

Workaround: After the cluster remediation operation has finished, perform one of the following tasks.

- Right-click the failed ESXi host and select *Reconfigure for vSphere HA*.
- Disable and re-enable vSphere HA for the cluster.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, disabling and re-enabling vSphere HA causes a vSphere HA error state

Disabling and re-enabling vSphere HA during remediation process of a cluster, may fail the remediation process due to vSphere HA health checks reporting that hosts don't have vSphere HA VIBs installed. You may see the following error message: `Setting desired image spec for cluster failed.`

Workaround: After the cluster remediation operation has finished, disable and re-enable vSphere HA for the cluster.

Checking for recommended images in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the recommendation generation task could take more than an hour to finish or may appear to hang. The completion time for the recommendation task depends on the number of devices configured on each host and the number of image candidates from the depot that vSphere Lifecycle Manager needs to process before obtaining a valid image to recommend.

Workaround: None.

Checking for hardware compatibility in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the validation report generation task could take up to 30 minutes to finish or may appear to hang. The completion time depends on the number of devices configured on each host and the number of hosts configured in the cluster.

Workaround: None

Incomplete error messages in non-English languages are displayed, when remediating a cluster in vSphere Lifecycle Manager

You can encounter incomplete error messages for localized languages in the vCenter Server user interface. The messages are displayed, after a cluster remediation process in vSphere Lifecycle Manager fails. For example, your can observe the following error message.

The error message in English language: `Virtual machine 'VMC on DELL EMC -FileServer' that runs on cluster 'Cluster-1' reported an issue which prevents entering maintenance mode: Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

The error message in French language: `La VM « VMC on DELL EMC -FileServer », située sur le cluster « {Cluster-1} », a signalé un problème empêchant le passage en mode de maintenance : Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

Workaround: None.

Importing an image with no vendor addon, components, or firmware and drivers addon to a cluster which image contains such elements, does not remove the image elements of the existing image

Only the ESXi base image is replaced with the one from the imported image.

Workaround: After the import process finishes, edit the image, and if needed, remove the vendor addon, components, and firmware and drivers addon.

When you convert a cluster that uses baselines to a cluster that uses a single image, a warning is displayed that vSphere HA VIBs will be removed

Converting a vSphere HA enabled cluster that uses baselines to a cluster that uses a single image, may result a warning message displaying that `vmware-fdm` component will be removed.

Workaround: This message can be ignored. The conversion process installs the `vmware-fdm` component.

If vSphere Update Manager is configured to download patch updates from the Internet through a proxy server, after upgrade to vSphere 7.0 that converts Update Manager to vSphere Lifecycle Manager, downloading patches from VMware patch repository might fail

In earlier releases of vCenter Server you could configure independent proxy settings for vCenter Server and vSphere Update Manager. After an upgrade to vSphere 7.0, vSphere Update Manager service becomes part of the vSphere Lifecycle Manager service. For the vSphere Lifecycle Manager service, the proxy settings are configured from the vCenter Server appliance settings. If you had configured Update Manager to download patch updates from the Internet through a proxy server but the vCenter Server appliance had no proxy setting configuration, after a vCenter Server upgrade to version 7.0, the vSphere Lifecycle Manager fails to connect to the VMware depot and is unable to download patches or updates.

Workaround: Log in to the vCenter Server Appliance Management Interface, https://*vcenter-server-appliance-FQDN-or-IP-address*:5480, to configure proxy settings for the vCenter Server appliance and enable vSphere Lifecycle Manager to use proxy.

Miscellaneous Issues

When applying a host profile with version 6.5 to a ESXi host with version 7.0, the compliance check fails

Applying a host profile with version 6.5 to a ESXi host with version 7.0, results in Coredump file profile reported as not compliant with the host.

Workaround: There are two possible workarounds.

1. When you create a host profile with version 6.5, set an advanced configuration option VMkernel.Boot.autoCreateDumpFile to false on the ESXi host.
2. When you apply an existing host profile with version 6.5, add an advanced configuration option VMkernel.Boot.autoCreateDumpFile in the host profile, configure the option to a fixed policy, and set value to false.

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit minor throughput degradation when Dynamic Receive Side Scaling (DYN_RSS) or Generic RSS (GEN_RSS) feature is turned on

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit less than 5 percent throughput degradation when DYN_RSS and GEN_RSS feature is turned on, which is unlikely to impact normal workloads.

Workaround: You can disable DYN_RSS and GEN_RSS feature with the following commands:

```
# esxcli system module parameters set -m nmlx5_core -p "DYN_RSS=0 GEN_RSS=0"
# reboot
```

RDMA traffic between two VMs on the same host might fail in PVRDMA environment

In a vSphere 7.0 implementation of a PVRDMA environment, VMs pass traffic through the HCA for local communication if an HCA is present. However, loopback of RDMA traffic does not work on qedrntv driver. For instance, RDMA Queue Pairs running on VMs that are configured under same uplink port cannot communicate with each other.

In vSphere 6.7 and earlier, HCA was used for local RDMA traffic if SRQ was enabled. vSphere 7.0 uses HCA loopback with VMs using versions of PVRDMA that have SRQ enabled with a minimum of HW v14 using RoCE v2.

The current version of Marvell FastLinQ adapter firmware does not support loopback traffic between QPs of the same PF or port.

Workaround: Required support is being added in the out-of-box driver certified for vSphere 7.0. If you are using the inbox qedrntv driver, you must use a 3-host configuration and migrate VMs to the third host.

Unreliable Datagram traffic QP limitations in qedrntv driver

There are limitations with the Marvell FastLinQ qedrntv RoCE driver and Unreliable Datagram (UD) traffic. UD applications involving bulk traffic might fail with qedrntv driver. Additionally, UD QPs can only work with DMA Memory Regions (MR). Physical MRs or FRMR are not supported. Applications attempting to use physical MR or FRMR along with UD QP fail to pass traffic when used with qedrntv driver. Known examples of such test applications are `ibv_ud_pingpong` and `ib_send_bw`.

Standard RoCE and RoCEv2 use cases in a VMware ESXi environment such as iSER, NVMe-oF (RoCE) and PVRDMA are not impacted by this issue. Use cases for UD traffic are limited and this issue impacts a small set of applications requiring bulk UD traffic.

Marvell FastLinQ hardware does not support RDMA UD traffic offload. In order to meet the VMware PVRDMA requirement to support GSI QP, a restricted software only implementation of UD QP support was added to the qedrntv driver. The goal of the implementation is to provide support for control path GSI communication and is not a complete implementation of UD QP supporting bulk traffic and advanced features.

Since UD support is implemented in software, the implementation might not keep up with heavy traffic and packets might be dropped. This can result in failures with bulk UD traffic.

Workaround: Bulk UD QP traffic is not supported with qedrntv driver and there is no workaround at this time. VMware ESXi RDMA (RoCE) use cases like iSER, NVMe, RDMA and PVRDMA are unaffected by this issue.

Servers equipped with QLogic 578xx NIC might fail when frequently connecting or disconnecting iSCSI LUNs

If you trigger QLogic 578xx NIC iSCSI connection or disconnection frequently in a short time, the server might fail due to an issue with the qfle3 driver. This is caused by a known defect in the device's firmware.

Workaround: None.

ESXi might fail during driver unload or controller disconnect operation in Broadcom NVMe over FC environment

In Broadcom NVMe over FC environment, ESXi might fail during driver unload or controller disconnect operation and display an error message such as: `@BlueScreen: #PF Exception 14 in world 2098707:vmknvmeGener IP 0x4200225021cc addr 0x19`

Workaround: None.

ESXi does not display OEM firmware version number of i350/X550 NICs on some Dell servers

The inbox ixgben driver only recognizes firmware data version or signature for i350/X550 NICs. On some Dell servers the OEM firmware version number is programmed into the OEM package version region, and the inbox ixgben driver does not read this information. Only the 8-digit firmware signature is displayed.

Workaround: To display the OEM firmware version number, install async ixgben driver version 1.7.15 or later.

X710 or XL710 NICs might fail in ESXi

When you initiate certain destructive operations to X710 or XL710 NICs, such as resetting the NIC or manipulating VMKernel's internal device tree, the NIC hardware might read data from non-packet memory.

Workaround: Do not reset the NIC or manipulate vmkernel internal device state.

NVMe-oF does not guarantee persistent VMHBA name after system reboot

NVMe-oF is a new feature in vSphere 7.0. If your server has a USB storage installation that uses vmhba30+ and also has NVMe over RDMA configuration, the VMHBA name might change after a system reboot. This is because the VMHBA name assignment for NVMe over RDMA is different from PCIe devices. ESXi does not guarantee persistence.

Workaround: None.

Backup fails for vCenter database size of 300 GB or greater

If the vCenter database size is 300 GB or greater, the file-based backup will fail with a timeout. The following error message is displayed: `Timeout! Failed to complete in 72000 seconds`

Workaround: None.

A restore of vCenter Server 7.0 which is upgraded from vCenter Server 6.x with External Platform Services Controller to vCenter Server 7.0 might fail

When you restore a vCenter Server 7.0 which is upgraded from 6.x with External Platform Services Controller to vCenter Server 7.0, the restore might fail and display the following error: `Failed to retrieve appliance storage list`

Workaround: During the first stage of the restore process, increase the storage level of the vCenter Server 7.0. For example if the vCenter Server 6.7 External Platform Services Controller setup storage type is small, select storage type large for the restore process.

Enabled SSL protocols configuration parameter is not configured during a host profile remediation process

`Enabled SSL protocols` configuration parameter is not configured during a host profile remediation and only the system default protocol `tlsv1.2` is enabled. This behavior is observed for a host profile with version 7.0 and earlier in a vCenter Server 7.0 environment.

Workaround: To enable TLSV 1.0 or TLSV 1.1 SSL protocols for SFCB, log in to an ESXi host by using SSH, and run the following ESXCLI command: `esxcli system wbem -P <protocol_name>`

Unable to configure Lockdown Mode settings by using Host Profiles

Lockdown Mode cannot be configured by using a security host profile and cannot be applied to multiple ESXi hosts at once. You must manually configure each host.

Workaround: In vCenter Server 7.0, you can configure Lockdown Mode and manage Lockdown Mode exception user list by using a security host profile.

When a host profile is applied to a cluster, Enhanced vMotion Compatibility (EVC) settings are missing from the ESXi hosts

Some settings in the VMware config file `/etc/vmware/config` are not managed by Host Profiles and are blocked, when the config file is modified. As a result, when the host profile is applied to a cluster, the EVC settings are lost, which causes loss of EVC functionalities. For example, unmasked CPUs can be exposed to workloads.

Workaround: Reconfigure the relevant EVC baseline on cluster to recover the EVC settings.

Using a host profile that defines a core dump partition in vCenter Server 7.0 results in an error

In vCenter Server 7.0, configuring and managing a core dump partition in a host profile is not available. Attempting to apply a host profile that defines a core dump partition, results in the following error: `No valid coredump partition found.`

Workaround: None. In vCenter Server 7.0., Host Profiles supports only file-based core dumps.

If you run the ESXCLI command to unload the firewall module, the hostd service fails and ESXi hosts lose connectivity

If you automate the firewall configuration in an environment that includes multiple ESXi hosts, and run the ESXCLI command `esxcli network firewall unload` that destroys filters and unloads the firewall module, the hostd service fails and ESXi hosts lose connectivity.

Workaround: Unloading the firewall module is not recommended at any time. If you must unload the firewall module, use the following steps:

1. Stop the hostd service by using the command:
   `/etc/init.d/hostd stop.`
2. Unload the firewall module by using the command:
   `esxcli network firewall unload.`
3. Perform the required operations.
4. Load the firewall module by using the command:
   `esxcli network firewall load.`
5. Start the hostd service by using the command:
   `/etc/init.d/hostd start.`

vSphere Storage vMotion operations might fail in a vSAN environment due to an unauthenticated session of the Network File Copy (NFC) manager

Migrations to a vSAN datastore by using vSphere Storage vMotion of virtual machines that have at least one snapshot and more than one virtual disk with different storage policy might fail. The issue occurs due to an unauthenticated session of the NFC manager because the Simple Object Access Protocol (SOAP) body exceeds the allowed size.

Workaround: First migrate the VM home namespace and just one of the virtual disks. After the operation completes, perform a disk only migration of the remaining 2 disks.

Changes in the properties and attributes of the devices and storage on an ESXi host might not persist after a reboot

If the device discovery routine during a reboot of an ESXi host times out, the jumpstart plug-in might not receive all configuration changes of the devices and storage from all the registered devices on the host. As a result, the process might restore the properties of some devices or storage to the default values after the reboot.

Workaround: Manually restore the changes in the properties of the affected device or storage.

If you use a beta build of ESXi 7.0, ESXi hosts might fail with a purple diagnostic screen during some lifecycle operations

If you use a beta build of ESXi 7.0, ESXi hosts might fail with a purple diagnostic screen during some lifecycle operations such as unloading a driver or switching between ENS mode and native driver mode. For example, if you try to change the ENS mode, in the backtrace you see an error message similar to: `case ENS::INTERRUPT::NoVM_DeviceStateWithGracefulRemove hit BlueScreen: ASSERT bora/vmkernel/main/dlmalloc.c:2733` This issue is specific for beta builds and does not affect release builds such as ESXi 7.0.

Workaround: Update to ESXi 7.0 GA.

You cannot create snapshots of virtual machines due to an error that a digest operation has failed

A rare race condition when an All-Paths-Down (APD) state occurs during the update of the Content Based Read Cache (CBRC) digest file might cause inconsistencies in the digest file. As a result, you cannot create virtual machine snapshots. You see an error such as `An error occurred while saving the snapshot: A digest operation has failed` in the backtrace.

Workaround: Power cycle the virtual machines to trigger a recompute of the CBRC hashes and clear the inconsistencies in the digest file.

If you upgrade your ESXi hosts to version 7.0 Update 3, but your vCenter Server is of an earlier version, Trusted Platform Module (TPM) attestation of the ESXi hosts fails

If you upgrade your ESXi hosts to version 7.0 Update 3, but your vCenter Server is of an earlier version, and you enable TPM, ESXi hosts fail to pass attestation. In the vSphere Client, you see the warning Host TPM attestation alarm. The Elliptic Curve Digital Signature Algorithm (ECDSA) introduced with ESXi 7.0 Update 3 causes the issue when vCenter Server is not of version 7.0 Update 3.

Workaround: Upgrade your vCenter Server to 7.0 Update 3 or acknowledge the alarm.

You see warnings in the boot loader screen about TPM asset tags

If a TPM-enabled ESXi host has no asset tag set on, you might see idle warning messages in the boot loader screen such as:

```
Failed to determine TPM asset tag size: Buffer too smallFailed to measure asset tag into TPM: Buffer too small
```

Workaround: Ignore the warnings or set an asset tag by using the command `$ esxcli hardware tpm tag set -d`

The sensord daemon fails to report ESXi host hardware status

A logic error in the IPMI SDR validation might cause `sensord` to fail to identify a source for power supply information. As a result, when you run the command `vsish -e get /power/hostStats`, you might not see any output.

Workaround: None

If an ESXi host fails with a purple diagnostic screen, the netdump service might stop working

In rare cases, if an ESXi host fails with a purple diagnostic screen, the netdump service might fail with an error such as `NetDump FAILED: Couldn't attach to dump server at IP x.x.x.x.`

Workaround: Configure the VMkernel core dump to use local storage.

You see frequent VMware Fault Domain Manager (FDM) core dumps on multiple ESXi hosts

In some environments, the number of datastores might exceed the FDM file descriptor limit. As a result, you see frequent core dumps on multiple ESXi hosts indicating FDM failure.

Workaround: Increase the FDM file descriptor limit to 2048. You can use the setting `das.config.fdm.maxFds` from the vSphere HA advanced options in the vSphere Client. For more information, see Set Advanced Options.

Virtual machines on a vSAN cluster with enabled NSX-T and a converged vSphere Distributed Switch (CVDS) in a VLAN transport zone cannot power on after a power off

If a secondary site is 95% disk full and VMs are powered off before simulating a secondary site failure, during recovery some of the virtual machines fail to power on. As a result, virtual machines become unresponsive. The issue occurs regardless if site recovery includes adding disks or ESXi hosts or CPU capacity.

Workaround: Select the virtual machines that do not power on and change the network to VM Network from Edit Settings on the VM context menu.

ESXI hosts might fail with a purple diagnostic screen with an error Assert at bora/modules/vmkernel/vmfs/fs6Journal.c:835

In rare cases, for example when running SESparse tests, the number of locks per transaction in a VMFS datastore might exceed the limit of 50 for the `J6_MAX_TXN_LOCKACTIONS` parameter. As a result, ESXi hosts might fail with a purple diagnostic screen with an error `Assert at bora/modules/vmkernel/vmfs/fs6Journal.c:835`.

Workaround: None

If you modify the netq_rss_ens parameter of the nmlx5_core driver, ESXi hosts might fail with a purple diagnostic screen

If you try to enable the `netq_rss_ens` parameter when you configure an enhanced data path on the `nmlx5_core` driver, ESXi hosts might fail with a purple diagnostic screen. The `netq_rss_ens` parameter, which enables NetQ RSS, is disabled by default with a value of `0`.

Workaround: Keep the default value for the `netq_rss_ens` module parameter in the `nmlx5_core` driver.

ESXi might terminate I/O to NVMeOF devices due to errors on all active paths

Occasionally, all active paths to NVMeOF device register I/O errors due to link issues or controller state. If the status of one of the paths changes to Dead, the High Performance Plug-in (HPP) might not select another path if it shows high volume of errors. As a result, the I/O fails.

Workaround: Disable the configuration option **/Misc/HppManageDegradedPaths** to unblock the I/O.

Upgrade to ESXi 7.0 Update 3 might fail due to changed name of the inbox i40enu network driver

Starting with vSphere 7.0 Update 3, the inbox i40enu network driver for ESXi changes name back to i40en. The i40en driver was renamed to i40enu in vSphere 7.0 Update 2, but the name change impacted some upgrade paths. For example, rollup upgrade of ESXi hosts that you manage with baselines and baseline groups from 7.0 Update 2 or 7.0 Update 2a to 7.0 Update 3 fails. In most cases, the i40enu driver upgrades to ESXi 7.0 Update 3 without any additional steps. However, if the driver upgrade fails, you cannot update ESXi hosts that you manage with baselines and baseline groups. You also cannot use host seeding or a vSphere Lifecycle Manager single image to manage the ESXi hosts. If you have already made changes related to the i40enu driver and devices in your system, before upgrading to ESXi 7.0 Update 3, you must uninstall the i40enu VIB or Component on ESXi, or first upgrade ESXi to ESXi 7.0 Update 2c.

Workaround: For more information, see VMware knowledge base article 85982.

SSH access fails after you upgrade to ESXi 7.0 Update 3d

After you upgrade to ESXi 7.0 Update 3d, SSH access might fail in certain conditions due to an update of OpenSSH to version 8.8.

Workaround: For more information, see VMware knowledge base article 88055.

USB device passthrough from ESXi hosts to virtual machines might fail

A USB modem device might simultaneously claim multiple interfaces by the VMkernel and block the device passthrough to VMs.

Workaround: You must apply the USB.quirks advanced configuration on the ESXi host to ignore the NET interface from VMkernel and allow the USB modem to passthrough to VMs. You can apply the configuration in 3 alternative ways:

1. Access the ESXi shell and run the following command: `esxcli system settings advanced set -o /USB/quirks -s 0xvvvv:0xpppp:0:0xffff:UQ_NET_IGNORE | |- Device Product ID |------- Device Vendor ID`
   For example, for the Gemalto M2M GmbH Zoom 4625 Modem(`vid:pid/1e2d:005b`), you can have the command `esxcli system settings advanced set` **-o** `/USB/quirks -s 0x1e2d:0x005b:0:0xffff:UQ_NET_IGNORE`
   Reboot the ESXi host.
2. Set the advanced configuration from the vSphere Client or the vSphere Web Client and reboot the ESXi host.
3. Use a Host Profile to apply the advanced configuration.

For more information on the steps, see VMware knowledge base article 80416.

HTTP requests from certain libraries to vSphere might be rejected

The HTTP reverse proxy in vSphere 7.0 enforces stricter standard compliance than in previous releases. This might expose pre-existing problems in some third-party libraries used by applications for SOAP calls to vSphere.

If you develop vSphere applications that use such libraries or include applications that rely on such libraries in your vSphere stack, you might experience connection issues when these libraries send HTTP requests to VMOMI. For example, HTTP requests issued from vijava libraries can take the following form:

```
POST /sdk HTTP/1.1
SOAPAction
Content-Type: text/xml; charset=utf-8
User-Agent: Java/1.8.0_221
```

The syntax in this example violates an HTTP protocol header field requirement that mandates a colon after SOAPAction. Hence, the request is rejected in flight.

Workaround: Developers leveraging noncompliant libraries in their applications can consider using a library that follows HTTP standards instead. For example, developers who use the vijava library can consider using the latest version of the yavijava library instead.

You might see a dump file when using Broadcom driver lsi_msgpt3, lsi_msgpt35 and lsi_mr3

When using the lsi_msgpt3, lsi_msgpt35 and lsi_mr3 controllers, there is a potential risk to see dump file lsuv2-lsi-drivers-plugin-util-zdump. There is an issue when exiting the storelib used in this plugin utility. There is no impact on ESXi operations, you can ignore the dump file.

Workaround: You can safely ignore this message. You can remove the lsuv2-lsi-drivers-plugin with the following command:

```
esxcli software vib remove -n lsuv2-lsiv2-drivers-plugin
```

You might see reboot is not required after configuring SR-IOV of a PCI device in vCenter, but device configurations made by third party extensions might be lost and require reboot to be re-applied.

In ESXi 7.0, SR-IOV configuration is applied without a reboot and the device driver is reloaded. ESXi hosts might have third party extensions perform device configurations that need to run after the device driver is loaded during boot. A reboot is required for those third party extensions to re-apply the device configuration.

Workaround: You must reboot after configuring SR-IOV to apply third party device configurations.

vSphere Client Issues

BIOS manufacturer displays as "--" in the vSphere Client

In the vSphere Client, when you select an ESXi host and navigate to **Configure** > **Hardware** > **Firmware**, you see `--` instead of the BIOS manufacturer name.

Workaround: For more information, see VMware knowledge base article 88937.

VMware ESXi 7.0 Update 3m Release Notes

This document contains the following sections

- Introduction
- What's New
- Earlier Releases of ESXi 7.0
- Patches Contained in This Release
- Patch Download and Installation
- Resolved Issues
- Known Issues from Previous Releases

Introduction

ESXi 7.0 Update 3m | MAY 03 2023 | Build 21686933 Check for additions and updates to these release notes.

IMPORTANT: If your source system contains hosts of versions between ESXi 7.0 Update 2 and Update 3c, and Intel drivers, before upgrading to ESXi 7.0 Update 3m, see the What's New section of the VMware vCenter Server 7.0 Update 3c Release Notes, because all content in the section is also applicable for vSphere 7.0 Update 3m. Also, see the related VMware knowledge base articles: 86447, 87258, and 87308.

What's New

- ESXi 7.0 Update 3m resolves issues about ESXi hosts losing network connectivity in certain environments and under specific conditions. For more information, see VMware knowledge base articles 91887 and 92035, and the Resolved Issues section.

Earlier Releases of ESXi 7.0

New features, resolved, and known issues of ESXi are described in the release notes for each release. Release notes for earlier releases of ESXi 7.0 are:

- VMware ESXi 7.0, ESXi 7.0 Update 3l Release Notes

- VMware ESXi 7.0, ESXi 7.0 Update 3k Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3j Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3i Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3g Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3f Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2a Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2 Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1b Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1a Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1 Release Notes
- VMware ESXi 7.0, ESXi 7.0b Release Notes

For internationalization, compatibility, and open source components, see the VMware vSphere 7.0 Release Notes.

Patches Contained in This Release

This release of ESXi 7.0 Update 3m delivers the following patches:

Build Details

Download Filename:	VMware-ESXi-7.0U3m-21686933-depot.zip
Build:	21686933
Download Size:	379.4 MB
md5sum:	9cd52571752b939637f80b351daace94
sha256checksum:	8c7892af03254259db28e7f2982be2802dcf66bdb2fc92e15a06fe7e7835b692
Host Reboot Required:	Yes
Virtual Machine Migration or Shutdown Required:	Yes

Components

Component	Bulletin	Category	Severity
ESXi Component - core ESXi VIBs	ESXi_7.0.3-0.90.21686933	Bugfix	Critical
ESXi Install/Upgrade Component	esx-update_7.0.3-0.90.21686933	Bugfix	Critical
Broadcom NetXtreme I ESX VMKAPI ethernet driver	Broadcom-ntg3_4.1.9.0-5vmw.703.0.90.21686933	Bugfix	Critical

IMPORTANT:

- Starting with vSphere 7.0, VMware uses components for packaging VIBs along with bulletins. The ESXi and esx-update bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.
- When patching ESXi hosts by using VMware Update Manager from a version prior to ESXi 7.0 Update 2, it is strongly recommended to use the rollup bulletin in the patch baseline. If you cannot use the rollup bulletin, be sure to include all of the following packages in the patching baseline. If the following packages are not included in the baseline, the update operation fails:
  - VMware-vmkusb_0.1-1vmw.701.0.0.16850804 or higher
  - VMware-vmkata_0.1-1vmw.701.0.0.16850804 or higher
  - VMware-vmkfcoe_1.0.0.2-1vmw.701.0.0.16850804 or higher
  - VMware-NVMeoF-RDMA_1.0.1.2-1vmw.701.0.0.16850804 or higher

Rollup Bulletin

This rollup bulletin contains the latest VIBs with all the fixes after the initial release of ESXi 7.0.

Bulletin ID	Category	Severity
ESXi70U3m-21686933	Bugfix	Critical

Image Profiles

VMware patch and update releases contain general and critical image profiles. Application of the general release image profile applies to new bug fixes.

Image Profile Name
ESXi-7.0U3m-21686933-standard
ESXi-7.0U3m-21686933-no-tools

ESXi Image

Name and Version	Release Date	Category	Detail
ESXi70U3m-21686933	MAY 03 2023	Bugfix	Bugfix image

Patch Download and Installation

Log in to the Broadcom Support Portal to download this patch.

For download instructions for earlier releases, see Download Broadcom products and software.

In vSphere 7.x, the Update Manager plug-in, used for administering vSphere Update Manager, is replaced with the Lifecycle Manager plug-in. Administrative operations for vSphere Update Manager are still available under the Lifecycle Manager plug-in, along with new capabilities for vSphere Lifecycle Manager.

The typical way to apply patches to ESXi 7.x hosts is by using the vSphere Lifecycle Manager. For details, see About vSphere Lifecycle Manager and vSphere Lifecycle Manager Baselines and Images.

You can also update ESXi hosts without using the Lifecycle Manager plug-in, and use an image profile instead. To do this, you must manually download the patch offline bundle ZIP file.

For details, see Upgrading Hosts by Using ESXCLI Commands, and the VMware ESXi Upgrade guide.

Resolved Issues

ESXi_7.0.3-0.90.21686933

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_bootbank_gc_7.0.3-0.90.21686933 • VMware_bootbank_esx-base_7.0.3-0.90.21686933 • VMware_bootbank_esx-dvfilter-generic-fastpath_7.0.3-0.90.21686933 • VMware_bootbank_native-misc-drivers_7.0.3-0.90.21686933 • VMware_bootbank_bmcal_7.0.3-0.90.21686933 • VMware_bootbank_esx-xserver_7.0.3-0.90.21686933 • VMware_bootbank_vsanhealth_7.0.3-0.90.21686933 • VMware_bootbank_vdfs_7.0.3-0.90.21686933 • VMware_bootbank_cpu-microcode_7.0.3-0.90.21686933 • VMware_bootbank_vsan_7.0.3-0.90.21686933 • VMware_bootbank_esxio-combiner_7.0.3-0.90.21686933 • VMware_bootbank_crx_7.0.3-0.90.21686933 • VMware_bootbank_trx_7.0.3-0.90.21686933
PRs Fixed	3164897
CVE numbers	N/A

This patch updates the **esx-base** VIB. Due to their dependency with the **esx-base** VIB, the following VIBs are updated with build number and patch version changes, but deliver no fixes: **gc, esx-dvfilter-generic-fastpath, native-misc-drivers, bmcal, esx-xserver, vsanhealth, vdfs, cpu-microcode, vsan, esxio-combiner, crx,** and **trx**. This patch resolves the following issue:

- **PR 3164897: After an upgrade to ESXi 7.0 Update 3l, some ESXi hosts and virtual machines connected to virtual switches might lose network**
  After an upgrade to ESXi 7.0 Update 3l, some ESXi hosts, their VMs, and other VMkernel ports, such as ports used by vSAN and vSphere Replication, which are connected to virtual switches, might lose connectivity due to an unexpected change in the NIC teaming policy. For example, the teaming policy on a portgroup might change to **Route Based on Originating Virtual Port** from **Route Based on IP Hash**. As a result, such a portgroup might lose network connectivity and some ESXi hosts and their VMs become inaccessible.
  This issue is resolved in this release.

esx-update_7.0.3-0.90.21686933

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMware_bootbank_loadesx_7.0.3-0.90.21686933

	• VMware_bootbank_esx-update_7.0.3-0.90.21686933
PRs Fixed	N/A
CVE numbers	N/A

Due to their dependency with the **esx-base** VIB, the following VIBs are updated with build number and patch version changes, but deliver no fixes: **loadesx** and **esx-update**.

Broadcom-ntg3_4.1.9.0-5vmw.703.0.90.21686933

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMW_bootbank_ntg3_4.1.9.0-5vmw.703.0.90.21686933
PRs Fixed	3182870
CVE numbers	N/A

Updates the **ntg3** VIB to resolve the following issue:

- **PR 3182870: After upgrading the ntg3 driver to version 4.1.9.0-4vmw, Broadcom NICs with fiber physical connectivity might lose network**
  Changes in the **ntg3** driver version **4.1.9.0-4vmw** might cause link issues for the fiber physical layer and connectivity on some NICs, such as Broadcom 1Gb, fails to come up.
  This issue is resolved in this release. ESXi 7.0 Update 3m provides **ntg3** driver version **4.1.9.0-5vmw**. The fix also adds a module parameter, **fifoElastic**, which you can enable in case of jumbo frame drops in certain Dell switches. To enable the parameter, use the following command:
  esxcli system module parameters set -p 'fifoElastic=1' -m ntg3

ESXi-7.0U3m-21686933-standard

ESXi70U3m-21686933

Name	ESXi
Version	ESXi70U3m-21686933
Release Date	May 03, 2023
Category	Bugfix
Affected Components	• ESXi Component - core ESXi VIBs • ESXi Install/Upgrade Component • Broadcom NetXtreme I ESX VMKAPI ethernet driver
PRs Fixed	3164897, 3182870
Related CVE numbers	N/A

Known Issues from Previous Releases

The earlier known issues are grouped as follows.

- vSAN Issues
- vSphere Cluster Services Issues
- Installation, Upgrade, and Migration Issues
- Security Features Issues
- Networking Issues
- Storage Issues
- vCenter Server and vSphere Client Issues
- Virtual Machine Management Issues
- vSphere HA and Fault Tolerance Issues
- vSphere Lifecycle Manager Issues
- Miscellaneous Issues
- vSphere Client Issues

vSAN Issues

If you change the preferred site in a VMware vSAN Stretched Cluster, some objects might incorrectly appear as compliant

If you change the preferred site in a stretched cluster, some objects might incorrectly appear as compliant, because their policy settings might not automatically change. For example, if you configure a virtual machine to keep data at the preferred site, when you change the preferred site, data might remain on the nonpreferred site.

Workaround: Before you change a preferred site, in Advanced Settings, lower the `ClomMaxCrawlCycleMinutes` setting to 15 min to make sure objects policies are updated. After the change, revert the `ClomMaxCrawlCycleMinutes` option to the earlier value.

vSphere Cluster Services Issues

You see compatibility issues in new vCLS VMs deployed in vSphere 7.0 Update 3 environment

The default name for new vCLS VMs deployed in vSphere 7.0 Update 3 environment uses the pattern vCLS-UUID. vCLS VMs created in earlier vCenter Server versions continue to use the pattern vCLS (n). Since the use of parenthesis () is not supported by many solutions that interoperate with vSphere, you might see compatibility issues.

Workaround: Reconfigure vCLS by using retreat mode after updating to vSphere 7.0 Update 3.

Installation, Upgrade, and Migration Issues

The vCenter Upgrade/Migration pre-checks fail with "Unexpected error 87"

The vCenter Server Upgrade/Migration pre-checks fail when the Security Token Service (STS) certificate does not contain a Subject Alternative Name (SAN) field. This situation occurs when you have replaced the vCenter 5.5 Single Sign-On certificate with a custom certificate that has no SAN field, and you attempt to upgrade to vCenter Server 7.0. The upgrade considers the STS certificate invalid and the pre-checks prevent the upgrade process from continuing.

Workaround: Replace the STS certificate with a valid certificate that contains a SAN field then proceed with the vCenter Server 7.0 Upgrade/Migration.

Problems upgrading to vSphere 7.0 with pre-existing CIM providers

After upgrade, previously installed 32-bit CIM providers stop working because ESXi requires 64-bit CIM providers. Customers may lose management API functions related to CIMPDK, NDDK (native DDK), HEXDK, VAIODK (IO filters), and see errors related to **uwglibc** dependency.

The syslog reports module missing, "32 bit shared libraries not loaded."

Workaround: There is no workaround. The fix is to download new 64-bit CIM providers from your vendor.

Installation of 7.0 Update 1 drivers on ESXi 7.0 hosts might fail

You cannot install drivers applicable to ESXi 7.0 Update 1 on hosts that run ESXi 7.0 or 7.0b.

The operation fails with an error, such as:

```
VMW_bootbank_qedrntv_3.40.4.0-12vmw.701.0.0.xxxxxxx requires vmkapi_2_7_0_0, but the requirement cannot be satisfied within the ImageProfile. Please refer to the log file for more details.
```

Workaround: Update the ESXi host to 7.0 Update 1. Retry the driver installation.

UEFI booting of ESXi hosts might stop with an error during an update to ESXi 7.0 Update 2 from an earlier version of ESXi 7.0

If you attempt to update your environment to 7.0 Update 2 from an earlier version of ESXi 7.0by using vSphere Lifecycle Manager patch baselines, UEFI booting of ESXi hosts might stop with an error such as:

```
Loading /boot.cfgFailed to load crypto64.efiFatal error: 15 (Not found)
```

Workaround: For more information, see VMware knowledge base articles 83063 and 83107 .

If legacy VIBs are in use on an ESXi host, vSphere Lifecycle Manager cannot extract a desired software specification to seed to a new cluster

With vCenter Server 7.0 Update 2, you can create a new cluster by importing the desired software specification from a single reference host. However, if legacy VIBs are in use on an ESXi host, vSphere Lifecycle Manager cannot extract in the vCenter Server instance where you create the cluster a reference software specification from such a host. In the `/var/log/lifecycle.log` , you see messages such as:

```
020-11-11T06:54:03Z lifecycle: 1000082644: HostSeeding:499
ERROR Extract depot failed: Checksum doesn't match. Calculated
5b404e28e83b1387841bb417da93c8c796ef2497c8af0f79583fd54e789d8826, expected:
0947542e30b794c721e21fb595f1851b247711d0619c55489a6a8cae6675e796 2020-11-11T06:54:04Z
lifecycle: 1000082644: imagemanagerctl:366 ERROR Extract depot failed.
2020-11-11T06:54:04Z lifecycle: 1000082644: imagemanagerctl:145 ERROR [VibChecksumError]
```

Workaround: Follow the steps described in VMware knowledge base article 83042.

You see a short burst of log messages in the syslog.log after every ESXi boot

After updating to ESXi 7.0 Update 2, you might see a short burst of log messages after every ESXi boot.

Such logs do not indicate any issue with ESXi and you can ignore these messages. For example:

```
2021-01-19T22:44:22Z watchdog-vaai-nasd: '/usr/lib/vmware/nfs/bin/vaai-nasd -f'
exited after 0 seconds (quick failure 127) 12021-01-19T22:44:22Z watchdog-vaai-
nasd: Executing '/usr/lib/vmware/nfs/bin/vaai-nasd -f'2021-01-19T22:44:22.990Z
aainasd[1000051135]: Log for VAAI-NAS Daemon for NFS version=1.0 build=build-00000
option=DEBUG2021-01-19T22:44:22.990Z vaainasd[1000051135]: DictionaryLoadFile: No entries

vaainasd[1000051135]: DISKLIB-PLUGIN : Not loading plugin /usr/lib/vmware/nas_plugins/
lib64: Not a shared library.
```

Workaround: None

You see warning messages for missing VIBs in vSphere Quick Boot compatibility check reports

After you upgrade to ESXi 7.0 Update 2, if you check vSphere Quick Boot compatibility of your environment by using the `/usr/lib/vmware/loadesx/bin/loadESXCheckCompat.py` command, you might see some warning messages for missing VIBs in the shell. For example:

```
Cannot find VIB(s) ... in the given VIB collection.Ignoring missing reserved VIB(s) ...,
they are removed from reserved VIB IDs.
```

Such warnings do not indicate a compatibility issue.

Workaround: The missing VIB messages can be safely ignored and do not affect the reporting of vSphere Quick Boot compatibility. The final output line of the `loadESXCheckCompat` command unambiguously indicates if the host is compatible.

Auto bootstrapping a cluster that you manage with a vSphere Lifecycle Manager image fails with an error

If you attempt auto bootstrapping a cluster that you manage with a vSphere Lifecycle Manager image to perform a stateful install and overwrite the VMFS partitions, the operation fails with an error. In the support bundle, you see messages such as:

```
2021-02-11T19:37:43Z Host Profiles[265671 opID=MainThread]: ERROR:
EngineModule::ApplyHostConfig. Exception: [Errno 30] Read-only file system
```

Workaround: Follow vendor guidance to clean the VMFS partition in the target host and retry the operation. Alternatively, use an empty disk. For more information on the disk-partitioning utility on ESXi, see VMware knowledge base article 1036609.

Upgrades to ESXi 7.x from 6.5.x and 6.7.0 by using ESXCLI might fail due to a space limitation

Upgrades to ESXi 7.x from 6.5.x and 6.7.0 by using the `esxcli software profile update` or `esxcli software profile install` ESXCLI commands might fail, because the ESXi bootbank might be less than the size of the image profile. In the ESXi Shell or the PowerCLI shell, you see an error such as:

```
[InstallationError]
The pending transaction requires 244 MB free space, however the maximum supported size is 239 MB.
Please refer to the log file for more details.
```

The issue also occurs when you attempt an ESXi host upgrade by using the ESXCLI commands `esxcli software vib update` or `esxcli software vib install`.

Workaround: You can perform the upgrade in two steps, by using the `esxcli software profile update` command to update ESXi hosts to ESXi 6.7 Update 1 or later, and then update to 7.0 Update 1c. Alternatively, you can run an upgrade by using an ISO image and the vSphere Lifecycle Manager.

You cannot migrate linked clones across vCenter Servers

If you migrate a linked clone across vCenter Servers, operations such as power on and delete might fail for the source virtual machine with an `Invalid virtual machine state` error.

Workaround: Keep linked clones on the same vCenter Server as the source VM. Alternatively, promote the linked clone to full clone before migration.

Migration across vCenter Servers of virtual machines with many virtual disks and snapshot levels to a datastore on NVMe over TCP storage might fail

Migration across vCenter Servers of virtual machines with more than 180 virtual disks and 32 snapshot levels to a datastore on NVMe over TCP storage might fail. The ESXi host preemptively fails with an error such as `The migration has exceeded the maximum switchover time of 100 second(s)`.

Workaround: None

A virtual machine with enabled Virtual Performance Monitoring Counters (VPMC) might fail to migrate between ESXi hosts

If you try to migrate a virtual machine with enabled VPMC by using vSphere vMotion, the operation might fail if the target host is using some of the counters to compute memory or performance statistics. The operation fails with an error such as `A performance counter used by the guest is not available on the host CPU`.

Workaround: Power off the virtual machine and use cold migration. For more information, see VMware knowledge base article 81191.

If a live VIB install, upgrade, or remove operation immediately precedes an interactive or scripted upgrade to ESXi 7.0 Update 3 by using the installer ISO, the upgrade fails

When a VIB install, upgrade, or remove operation immediately precedes an interactive or scripted upgrade to ESXi 7.0 Update 3 by using the installer ISO, the ConfigStore might not keep some configurations of the upgrade. As a result, ESXi hosts become inaccessible after the upgrade operation, although the upgrade seems successful. To prevent this issue, the ESXi 7.0 Update 3 installer adds a temporary check to block such scenarios. In the ESXi installer console, you see the following error message: `Live VIB installation, upgrade or removal may cause subsequent ESXi upgrade to fail when using the ISO installer`.

Workaround: Use an alternative upgrade method to avoid the issue, such as using ESXCLI or the vSphere Lifecycle Manager.

Smart Card and RSA SecurID authentication might stop working after upgrading to vCenter Server 7.0

If you have configured vCenter Server for either Smart Card or RSA SecurID authentication, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057 before starting the vSphere 7.0 upgrade process. If you do not perform the workaround as described in the KB, you might see the following error messages and Smart Card or RSA SecurID authentication does not work.

"Smart card authentication may stop working. Smart card settings may not be preserved, and smart card authentication may stop working."

or

"RSA SecurID authentication may stop working. RSA SecurID settings may not be preserved, and RSA SecurID authentication may stop working."

Workaround: Before upgrading to vSphere 7.0, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057.

The vlanid property in custom installation scripts might not work

If you use a custom installation script that sets the `vlanid` property to specify a desired VLAN, the property might not take effect on newly installed ESXi hosts. The issue occurs only when a physical NIC is already connected to DHCP when the installation starts. The `vlanid` property works properly when you use a newly connected NIC.

Workaround: Manually set the VLAN from the Direct Console User Interface after you boot the ESXi host. Alternatively, disable the physical NIC and then boot the host.

HPE servers with Trusted Platform Module (TPM) boot, but remote attestation fails

Some HPE servers do not have enough event log space to properly finish TPM remote attestation. As a result, the VMkernel boots, but remote attestation fails due to the truncated log.

Workaround: None.

Upgrading a vCenter Server with an external Platform Services Controller from 6.7u3 to 7.0 fails with VMAFD error

When you upgrade a vCenter Server deployment using an external Platform Services Controller, you converge the Platform Services Controller into a vCenter Server appliance. If the upgrade fails with the error `install.vmafd.vmdir_vdcpromo_error_21` , the VMAFD firstboot process has failed. The VMAFD firstboot process copies the VMware Directory Service Database (data.mdb) from the source Platform Services Controller and replication partner vCenter Server appliance.

Workaround: Disable TCP Segmentation Offload (TSO) and Generic Segmentation Offload (GSO) on the Ethernet adapter of the source Platform Services Controller or replication partner vCenter Server appliance before upgrading a vCenter Server with an external Platform Services Controller. See Knowledge Base article: https://kb.vmware.com/s/article/74678

Smart card and RSA SecurID settings may not be preserved during vCenter Server upgrade

Authentication using RSA SecurID will not work after upgrading to vCenter Server 7.0. An error message will alert you to this issue when attempting to login using your RSA SecurID login.

Workaround: Reconfigure the smart card or RSA SecureID.

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with network error message

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with the error message `IP already exists in the network`. This prevents the migration process from configuring the network parameters on the new vCenter Server appliance. For more information, examine the log file: `/var/log/vmware/upgrade/UpgradeRunner.log`

Workaround:

1. Verify that all Windows Updates have been completed on the source vCenter Server for Windows instance, or disable automatic Windows Updates until after the migration finishes.
2. Retry the migration of vCenter Server for Windows to vCenter Server appliance 7.0.

When you configure the number of virtual functions for an SR-IOV device by using the max_vfs module parameter, the changes might not take effect

In vSphere 7.0, you can configure the number of virtual functions for an SR-IOV device by using the Virtual Infrastructure Management (VIM) API, for example, through the vSphere Client. The task does not require reboot of the ESXi host. After you use the VIM API configuration, if you try to configure the number of SR-IOV virtual functions by using the `max_vfs` module parameter, the changes might not take effect because they are overridden by the VIM API configuration.

Workaround: None. To configure the number of virtual functions for an SR-IOV device, use the same method every time. Use the VIM API or use the `max_vfs` module parameter and reboot the ESXi host.

Upgraded vCenter Server appliance instance does not retain all the secondary networks (NICs) from the source instance

During a major upgrade, if the source instance of the vCenter Server appliance is configured with multiple secondary networks other than the VCHA NIC, the target vCenter Server instance will not retain secondary networks other than the VCHA NIC. If the source instance is configured with multiple NICs that are part of VDS port groups, the NIC configuration will not be preserved during the upgrade. Configurations for vCenter Server appliance instances that are part of the standard port group will be preserved.

Workaround: None. Manually configure the secondary network in the target vCenter Server appliance instance.

After upgrading or migrating a vCenter Server with an external Platform Services Controller, users authenticating using Active Directory lose access to the newly upgraded vCenter Server instance

After upgrading or migrating a vCenter Server with an external Platform Services Controller, if the newly upgraded vCenter Server is not joined to an Active Directory domain, users authenticating using Active Directory will lose access to the vCenter Server instance.

Workaround: Verify that the new vCenter Server instance has been joined to an Active Directory domain. See Knowledge Base article: https://kb.vmware.com/s/article/2118543

Migrating a vCenter Server for Windows with an external Platform Services Controller using an Oracle database fails

If there are non-ASCII strings in the Oracle events and tasks table the migration can fail when exporting events and tasks data. The following error message is provided: UnicodeDecodeError

Workaround: None.

After an ESXi host upgrade, a Host Profile compliance check shows non-compliant status while host remediation tasks fail

The non-compliant status indicates an inconsistency between the profile and the host.

This inconsistency might occur because ESXi 7.0 does not allow duplicate claim rules, but the profile you use contains duplicate rules. For example, if you attempt to use the Host Profile that you extracted from the host before upgrading ESXi 6.5 or ESXi 6.7 to version 7.0 and the Host Profile contains any duplicate claim rules of system default rules, you might experience the problems.

Workaround:

1. Remove any duplicate claim rules of the system default rules from the Host Profile document.

2. Check the compliance status.
3. Remediate the host.
4. If the previous steps do not help, reboot the host.

Error message displays in the vCenter Server Management Interface

After installing or upgrading to vCenter Server 7.0, when you navigate to the Update panel within the vCenter Server Management Interface, the error message "Check the URL and try again" displays. The error message does not prevent you from using the functions within the Update panel, and you can view, stage, and install any available updates.

Workaround: None.

Security Features Issues

Turn off the Service Location Protocol service in ESXi, slpd, to prevent potential security vulnerabilities

Some services in ESXi that run on top of the host operating system, including slpd, the CIM object broker, sfcbd, and the related openwsmand service, have proven security vulnerabilities. VMware has addressed all known vulnerabilities in VMSA-2019-0022 and VMSA-2020-0023, and the fixes are part of the vSphere 7.0 Update 2 release. While sfcbd and openwsmand are disabled by default in ESXi, slpd is enabled by default and you must turn it off, if not necessary, to prevent exposure to a future vulnerability after an upgrade.

Workaround: To turn off the slpd service, run the following PowerCLI commands:

```
$ Get-VMHost | Get-VmHostService | Where-Object {$_.key -eq "slpd"} | Set-VMHostService -policy "off"$ Get-VMHost | Get-VmHostService | Where-Object {$_.key -eq "slpd"} | Stop-VMHostService -Confirm:$false
```

Alternatively, you can use the command `chkconfig slpd off && /etc/init.d/slpd stop`.

The openwsmand service is not on the ESXi services list and you can check the service state by using the following PowerCLI commands:

```
$esx=(Get-EsxCli -vmhost xx.xx.xx.xx -v2)$esx.system.process.list.invoke() | where CommandLine -like '*openwsman*' | select commandline
```

In the ESXi services list, the sfcbd service appears as sfcbd-watchdog.

For more information, see VMware knowledge base articles 76372 and 1025757.

Encrypted virtual machine fails to power on when HA-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled HA on the Trusted Cluster and one or more hosts in the cluster fails attestation, an encrypted virtual machine cannot power on.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Encrypted virtual machine fails to power on when DRS-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled DRS on the Trusted Cluster and one or more hosts in the cluster fails attestation, DRS might try to power on an encrypted virtual machine on an unattested host in the cluster. This operation puts the virtual machine in a locked state.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Migrating or cloning encrypted virtual machines across vCenter Server instances fails when attempting to do so using the vSphere Client

If you try to migrate or clone an encrypted virtual machine across vCenter Server instances using the vSphere Client, the operation fails with the following error message: "The operation is not allowed in the current state."

Workaround: You must use the vSphere APIs to migrate or clone encrypted virtual machines across vCenter Server instances.

Networking Issues

Reduced throughput in networking performance on Intel 82599/X540/X550 NICs

The new queue-pair feature added to ixgben driver to improve networking performance on Intel 82599EB/X540/X550 series NICs might reduce throughput under some workloads in vSphere 7.0 as compared to vSphere 6.7.

Workaround: To achieve the same networking performance as vSphere 6.7, you can disable the queue-pair with a module parameter. To disable the queue-pair, run the command:

```
# esxcli system module parameters set -p "QPair=0,0,0,0..." -m ixgben
```

After running the command, reboot.

One or more I/O devices do not generate interrupts when the AMD IOMMU is in use

If the I/O devices on your ESXi host provide more than a total of 512 distinct interrupt sources, some sources are erroneously assigned an interrupt-remapping table entry (IRTE) index in the AMD IOMMU that is greater than the maximum value. Interrupts from such a source are lost, so the corresponding I/O device behaves as if interrupts are disabled.

Workaround: Use the ESXCLI command `esxcli system settings kernel set -s iovDisableIR -v true` to disable the AMD IOMMU interrupt remapper. Reboot the ESXi host so that the command takes effect.

When you set auto-negotiation on a network adapter, the device might fail

In some environments, if you set link speed to auto-negotiation for network adapters by using the command `esxcli network nic set -a -n vmmicx`, the devices might fail and reboot does not recover connectivity. The issue is specific to a combination of some Intel X710/X722 network adapters, a SFP+ module and a physical switch, where auto-negotiate speed/duplex scenario is not supported.

Workaround: Make sure you use an Intel-branded SFP+ module. Alternatively, use a Direct Attach Copper (DAC) cable.

Solarflare x2542 and x2541 network adapters configured in 1x100G port mode achieve throughput of up to 70Gbps in a vSphere environment

vSphere 7.0 Update 2 supports Solarflare x2542 and x2541 network adapters configured in 1x100G port mode. However, you might see a hardware limitation in the devices that causes the actual throughput to be up to some 70Gbps in a vSphere environment.

Workaround: None

VLAN traffic might fail after a NIC reset

A NIC with PCI device ID 8086:1537 might stop to send and receive VLAN tagged packets after a reset, for example, with a command `vsish -e set /net/pNics/vmnic0/reset 1`.

Workaround: Avoid resetting the NIC. If you already face the issue, use the following commands to restore the VLAN capability, for example at vmnic0:

```
# esxcli network nic software set --tagging=1 -n vmnic0# esxcli network nic software set --tagging=0 -n vmnic0
```

Any change in the NetQueue balancer settings causes NetQueue to be disabled after an ESXi host reboot

Any change in the NetQueue balancer settings by using the command `esxcli/localcli network nic queue loadbalancer set -n <nicname> --<lb_setting>` causes NetQueue, which is enabled by default, to be disabled after an ESXi host reboot.

Workaround: After a change in the NetQueue balancer settings and host reboot, use the command `configstorecli config current get -c esx -g network -k nics` to retrieve ConfigStore data to verify whether the `/esx/network/nics/net_queue/load_balancer/enable` is working as expected.

After you run the command, you see output similar to:

```
{"mac": "02:00:0e:6d:14:3e","name": "vmnic1","net_queue": { "load_balancer":
{ "dynamic_pool": true, "enable": true }},"virtual_mac": "00:50:56:5a:21:11"}
```

If the output is not as expected, for example `"load_balancer": "enable": false"` , run the following command:

```
esxcli/localcli network nic queue loadbalancer state set -n <nicname> -e true
```

Paravirtual RDMA (PVRDMA) network adapters do not support NSX networking policies

If you configure an NSX distributed virtual port for use in PVRDMA traffic, the RDMA protocol traffic over the PVRDMA network adapters does not comply with the NSX network policies.

Workaround: Do not configure NSX distributed virtual ports for use in PVRDMA traffic.

Rollback from converged vSphere Distributed Switch (VDS) to NSX-T VDS is not supported in vSphere 7.0 Update 3

Rollback from converged VDS that supports both vSphere 7 traffic and NSX-T 3 traffic on the same VDS to one N-VDS for NSX-T traffic is not supported in vSphere 7.0 Update 3.

Workaround: None

If you do not set the nmlx5 network driver module parameter, network connectivity or ESXi hosts might fail

If you do not set the `supported_num_ports` module parameter for the `nmlx5_core` driver on an ESXi host with multiple network adapters of versions Mellanox ConnectX-4, Mellanox ConnectX-5 and Mellanox ConnectX-6, the driver might not allocate sufficient memory for operating all the NIC ports for the host. As a result, you might experience network loss or ESXi host failure with purple diagnostic screen, or both.

Workaround: Set the `supported_num_ports` module parameter value in the `nmlx5_core` network driver equal to the total number of Mellanox ConnectX-4, Mellanox ConnectX-5 and Mellanox ConnectX-6 network adapter ports on the ESXi host.

High throughput virtual machines may experience degradation in network performance when Network I/O Control (NetIOC) is enabled

Virtual machines requiring high network throughput can experience throughput degradation when upgrading from vSphere 6.7 to vSphere 7.0 with NetIOC enabled.

Workaround: Adjust the `ethernetx.ctxPerDev` setting to enable multiple worlds.

IPv6 traffic fails to pass through VMkernel ports using IPsec

When you migrate VMkernel ports from one port group to another, IPv6 traffic does not pass through VMkernel ports using IPsec.

Workaround: Remove the IPsec security association (SA) from the affected server, and then reapply the SA. To learn how to set and remove an IPsec SA, see the *vSphere Security* documentation.

Higher ESX network performance with a portion of CPU usage increase

ESX network performance may increase with a portion of CPU usage.

Workaround: Remove and add the network interface with only 1 rx dispatch queue. For example:

```
esxcli network ip interface remove --interface-name=vmk1
```

```
esxcli network ip interface add --interface-name=vmk1 --num-rxqueue=1
```

VM might lose Ethernet traffic after hot-add, hot-remove or storage vMotion

A VM might stop receiving Ethernet traffic after a hot-add, hot-remove or storage vMotion. This issue affects VMs where the uplink of the VNIC has SR-IOV enabled. PVRDMA virtual NIC exhibits this issue when the uplink of the virtual network is a Mellanox RDMA capable NIC and RDMA namespaces are configured.

Workaround: You can hot-remove and hot-add the affected Ethernet NICs of the VM to restore traffic. On Linux guest operating systems, restarting the network might also resolve the issue. If these workarounds have no effect, you can reboot the VM to restore network connectivity.

Change of IP address for a VCSA deployed with static IP address requires that you create the DNS records in advance

With the introduction of the DDNS, the DNS record update only works for VCSA deployed with DHCP configured networking. While changing the IP address of the vCenter server via VAMI, the following error is displayed:

The specified IP address does not resolve to the specified hostname.

Workaround: There are two possible workarounds.

1. Create an additional DNS entry with the same FQDN and desired IP address. Log in to the VAMI and follow the steps to change the IP address.
2. Log in to the VCSA using ssh. Execute the following script:
   `./opt/vmware/share/vami/vami_config_net`
   Use option 6 to change the IP adddress of eth0. Once changed, execute the following script:
   `./opt/likewise/bin/lw-update-dns`
   Restart all the services on the VCSA to update the IP information on the DNS server.

It may take several seconds for the NSX Distributed Virtual Port Group (NSX DVPG) to be removed after deleting the corresponding logical switch in NSX Manager.

As the number of logical switches increases, it may take more time for the NSX DVPG in vCenter Server to be removed after deleting the corresponding logical switch in NSX Manager. In an environment with 12000 logical switches, it takes approximately 10 seconds for an NSX DVPG to be deleted from vCenter Server.

Workaround: None.

Hostd runs out of memory and fails if a large number of NSX Distributed Virtual port groups are created.

In vSphere 7.0, NSX Distributed Virtual port groups consume significantly larger amounts of memory than opaque networks. For this reason, NSX Distributed Virtual port groups can not support the same scale as an opaque network given the same amount of memory.

Workaround:To support the use of NSX Distributed Virtual port groups, increase the amount of memory in your ESXi hosts. If you verify that your system has adequate memory to support your VMs, you can directly increase the memory of `hostd` using the following command.

```
localcli --plugin-dir /usr/lib/vmware/esxcli/int/ sched group setmemconfig --group-path
host/vim/vmvisor/hostd --units mb --min 2048 --max 2048
```

Note that this will cause `hostd` to use memory normally reserved for your environment's VMs. This may have the affect of reducing the number of VMs your ESXi host can support.

DRS may incorrectly launch vMotion if the network reservation is configured on a VM

If the network reservation is configured on a VM, it is expected that DRS only migrates the VM to a host that meets the specified requirements. In a cluster with NSX transport nodes, if some of the transport nodes join the transport zone by NSX-T Virtual Distributed Switch (N-VDS), and others by vSphere Distributed Switch (VDS) 7.0, DRS may incorrectly launch vMotion. You might encounter this issue when:

- The VM connects to an NSX logical switch configured with a network reservation.
- Some transport nodes join transport zone using N-VDS, and others by VDS 7.0, or, transport nodes join the transport zone through different VDS 7.0 instances.

Workaround: Make all transport nodes join the transport zone by N-VDS or the same VDS 7.0 instance.

When adding a VMkernel NIC (vmknic) to an NSX portgroup, vCenter Server reports the error "Connecting VMKernel adapter to a NSX Portgroup on a Stateless host is not a supported operation. Please use Distributed Port Group instead."

- For stateless ESXi on Distributed Virtual Switch (VDS), the vmknic on a NSX port group is blocked. You must instead use a Distributed Port Group.
- For stateful ESXi on VDS, vmknic on NSX port group is supported, but vSAN may have an issue if it is using vmknic on a NSX port group.

Workaround: Use a Distributed Port Group on the same VDS.

Enabling SRIOV from vCenter for QLogic 4x10GE QL41164HFCU CNA might fail

If you navigate to the **Edit Settings** dialog for physical network adapters and attempt to enable SR-IOV, the operation might fail when using QLogic 4x10GE QL41164HFCU CNA. Attempting to enable SR-IOV might lead to a network outage of the ESXi host.

Workaround: Use the following command on the ESXi host to enable SRIOV:

```
esxcfg-module
```

vCenter Server fails if the hosts in a cluster using Distributed Resource Scheduler (DRS) join NSX-T networking by a different Virtual Distributed Switch (VDS) or combination of NSX-T Virtual Distributed Switch (NVDS) and VDS

In vSphere 7.0, when using NSX-T networking on vSphere VDS with a DRS cluster, if the hosts do not join the NSX transport zone by the same VDS or NVDS, it can cause vCenter Server to fail.

Workaround: Have hosts in a DRS cluster join the NSX transport zone using the same VDS or NVDS.

Storage Issues

VMFS datastores are not mounted automatically after disk hot remove and hot insert on HPE Gen10 servers with SmartPQI controllers

When SATA disks on HPE Gen10 servers with SmartPQI controllers without expanders are hot removed and hot inserted back to a different disk bay of the same machine, or when multiple disks are hot removed and hot inserted back in a different order, sometimes a new local name is assigned to the disk. The VMFS datastore on that disk appears as a snapshot and will not be mounted back automatically because the device name has changed.

Workaround: None. SmartPQI controller does not support unordered hot remove and hot insert operations.

VOMA check on NVMe based VMFS datastores fails with error

VOMA check is not supported for NVMe based VMFS datastores and will fail with the error:

```
ERROR: Failed to reserve device. Function not implemented
```

Example:

```
# voma -m vmfs -f check -d /vmfs/devices/disks/: <partition#>
Running VMFS Checker version 2.1 in check mode
Initializing LVM metadata, Basic Checks will be done

Checking for filesystem activity
Performing filesystem liveness check..|Scanning for VMFS-6 host activity (4096 bytes/HB, 1024 HBs).
ERROR: Failed to reserve device. Function not implemented
Aborting VMFS volume check
VOMA failed to check device : General Error
```

Workaround: None. If you need to analyse VMFS metadata, collect it using the `-l` option, and pass to VMware customer support. The command for collecting the dump is:

```
voma -l -f dump -d /vmfs/devices/disks/:<partition#>
```

Using the VM reconfigure API to attach an encrypted First Class Disk to an encrypted virtual machine might fail with error

If an FCD and a VM are encrypted with different crypto keys, your attempts to attach the encrypted FCD to the encrypted VM using the `VM reconfigure API` might fail with the error message:

```
Cannot decrypt disk because key or password is incorrect.
```

Workaround: Use the `attachDisk API` rather than the `VM reconfigure API` to attach an encrypted FCD to an encrypted VM.

ESXi host might get in non responding state if a non-head extent of its spanned VMFS datastore enters the Permanent Device Loss (PDL) state

This problem does not occur when a non-head extent of the spanned VMFS datastore fails along with the head extent. In this case, the entire datastore becomes inaccessible and no longer allows I/Os.

In contrast, when only a non-head extent fails, but the head extent remains accessible, the datastore heartbeat appears to be normal. And the I/Os between the host and the datastore continue. However, any I/Os that depend on the failed non-head extent start failing as well. Other I/O transactions might accumulate while waiting for the failing I/Os to resolve, and cause the host to enter the non responding state.

Workaround: Fix the PDL condition of the non-head extent to resolve this issue.

Virtual NVMe Controller is the default disk controller for Windows 10 guest operating systems

The Virtual NVMe Controller is the default disk controller for the following guest operating systems when using Hardware Version 15 or later:

Windows 10

Windows Server 2016

Windows Server 2019

Some features might not be available when using a Virtual NVMe Controller. For more information, see https://kb.vmware.com/s/article/2147714

Note: Some clients use the previous default of LSI Logic SAS. This includes ESXi host client and PowerCLI.

Workaround: If you need features not available on Virtual NVMe, switch to VMware Paravirtual SCSI (PVSCSI) or LSI Logic SAS. For information on using VMware Paravirtual SCSI (PVSCSI), see https://kb.vmware.com/s/article/1010398

After an ESXi host upgrade to vSphere 7.0, presence of duplicate core claim rules might cause unexpected behavior

Claim rules determine which multipathing plugin, such as NMP, HPP, and so on, owns paths to a particular storage device. ESXi 7.0 does not support duplicate claim rules. However, the ESXi 7.0 host does not alert you if you add duplicate rules to the existing claim rules inherited through an upgrade from a legacy release. As a result of using duplicate rules, storage devices might be claimed by unintended plugins, which can cause unexpected outcome.

Workaround: Do not use duplicate core claim rules. Before adding a new claim rule, delete any existing matching claim rule.

A CNS query with the compliance status filter set might take unusually long time to complete

The CNS QueryVolume API enables you to obtain information about the CNS volumes, such as volume health and compliance status. When you check the compliance status of individual volumes, the results are obtained quickly. However, when you invoke the CNS QueryVolume API to check the compliance status of multiple volumes, several tens or hundreds, the query might perform slowly.

Workaround: Avoid using bulk queries. When you need to get compliance status, query one volume at a time or limit the number of volumes in the query API to 20 or fewer. While using the query, avoid running other CNS operations to get the best performance.

A VMFS datastore backed by an NVMe over Fabrics namespace or device might become permanently inaccessible after recovering from an APD or PDL failure

If a VMFS datastore on an ESXi host is backed by an NVMe over Fabrics namespace or device, in case of an all paths down (APD) or permanent device loss (PDL) failure, the datastore might be inaccessible even after recovery. You cannot access the datastore from either the ESXi host or the vCenter Server system.

Workaround: To recover from this state, perform a rescan on a host or cluster level. For more information, see Perform Storage Rescan.

Deleted CNS volumes might temporarily appear as existing in the CNS UI

After you delete an FCD disk that backs a CNS volume, the volume might still show up as existing in the CNS UI. However, your attempts to delete the volume fail. You might see an error message similar to the following:

```
The object or item referred to could not be found.
```

Workaround: The next full synchronization will resolve the inconsistency and correctly update the CNS UI.

Attempts to attach multiple CNS volumes to the same pod might occasionally fail with an error

When you attach multiple volumes to the same pod simultaneously, the attach operation might occasionally choose the same controller slot. As a result, only one of the operations succeeds, while other volume mounts fail.

Workaround: After Kubernetes retries the failed operation, the operation succeeds if a controller slot is available on the node VM.

Under certain circumstances, while a CNS operation fails, the task status appears as successful in the vSphere Client

This might occur when, for example, you use an incompliant storage policy to create a CNS volume. The operation fails, while the vSphere Client shows the task status as successful.

Workaround: The successful task status in the vSphere Client does not guarantee that the CNS operation succeeded. To make sure the operation succeeded, verify its results.

Unsuccessful delete operation for a CNS persistent volume might leave the volume undeleted on the vSphere datastore

This issue might occur when the CNS Delete API attempts to delete a persistent volume that is still attached to a pod. For example, when you delete the Kubernetes namespace where the pod runs. As a result, the volume gets cleared from CNS and the CNS query operation does not return the volume. However, the volume continues to reside on the datastore and cannot be deleted through the repeated CNS Delete API operations.

Workaround: None.

vCenter Server and vSphere Client Issues

Vendor providers go offline after a PNID change

When you change the vCenter IP address (PNID change), the registered vendor providers go offline.

Workaround: Re-register the vendor providers.

Cross vCenter migration of a virtual machine fails with an error

When you use cross vCenter vMotion to move a VM's storage and host to a different vCenter server instance, you might receive the error `The operation is not allowed in the current state.`

This error appears in the UI wizard after the Host Selection step and before the Datastore Selection step, in cases where the VM has an assigned storage policy containing host-based rules such as encryption or any other IO filter rule.

Workaround: Assign the VM and its disks to a storage policy without host-based rules. You might need to decrypt the VM if the source VM is encrypted. Then retry the cross vCenter vMotion action.

Storage Sensors information in Hardware Health tab shows incorrect values on vCenter UI, host UI, and MOB

When you navigate to **Host > Monitor > Hardware Health > Storage Sensors** on vCenter UI, the storage information displays either incorrect or unknown values. The same issue is observed on the host UI and the MOB path `"runtime.hardwareStatusInfo.storageStatusInfo"` as well.

Workaround: None.

vSphere UI host advanced settings shows the current product locker location as empty with an empty default

vSphere UI host advanced settings shows the current product locker location as empty with an empty default. This is inconsistent as the actual product location `symlink` is created and valid. This causes confusion to the user. The default cannot be corrected from UI.

Workaround: User can use the esxcli command on the host to correct the current product locker location default as below.

1. Remove the existing Product Locker Location setting with: "`esxcli system settings advanced remove -o ProductLockerLocation`"

2. Re-add the Product Locker Location setting with the appropriate default:

2.a. If the ESXi is a full installation, the default value is "`/locker/packages/vmtoolsRepo`" `export PRODUCT_LOCKER_DEFAULT="/locker/packages/vmtoolsRepo"`

2.b. If the ESXi is a PXEboot configuration such as autodeploy, the default value is: "`/vmtoolsRepo`" `export PRODUCT_LOCKER_DEFAULT="/vmtoolsRepo"`

Run the following command to automatically figure out the location: `export PRODUCT_LOCKER_DEFAULT=`readlink /productLocker``

Add the setting: `esxcli system settings advanced add -d "Path to VMware Tools repository" -o ProductLockerLocation -t string -s $PRODUCT_LOCKER_DEFAULT`

You can combine all the above steps in step 2 by issuing the single command:

```
esxcli system settings advanced add -d "Path to VMware Tools repository" -o
ProductLockerLocation -t string -s `readlink /productLocker`
```

Linked Software-Defined Data Center (SDDC) vCenter Server instances appear in the on-premises vSphere Client if a vCenter Cloud Gateway is linked to the SDDC.

When a vCenter Cloud Gateway is deployed in the same environment as an on-premises vCenter Server, and linked to an SDDC, the SDDC vCenter Server will appear in the on-premises vSphere Client. This is unexpected behavior and the linked SDDC vCenter Server should be ignored. All operations involving the linked SDDC vCenter Server should be performed on the vSphere Client running within the vCenter Cloud Gateway.

Workaround: None.

Virtual Machine Management Issues

UEFI HTTP booting of virtual machines on ESXi hosts of version earlier than 7.0 Update 2 fails

UEFI HTTP booting of virtual machines is supported only on hosts of version ESXi 7.0 Update 2 and later and VMs with HW version 19 or later.

Workaround: Use UEFI HTTP booting only in virtual machines with HW version 19 or later. Using HW version 19 ensures the virtual machines are placed only on hosts with ESXi version 7.0 Update 2 or later.

Virtual machine snapshot operations fail in vSphere Virtual Volumes datastores on Purity version 5.3.10

Virtual machine snapshot operations fail in vSphere Virtual Volumes datastores on Purity version 5.3.10 with an error such as `An error occurred while saving the snapshot: The VVol target encountered a vendor specific error`. The issue is specific for Purity version 5.3.10.

Workaround: Upgrade to Purity version 6.1.7 or follow vendor recommendations.

The postcustomization section of the customization script runs before the guest customization

When you run the guest customization script for a Linux guest operating system, the `precustomization` section of the customization script that is defined in the customization specification runs before the guest customization and the `postcustomization` section runs after that. If you enable Cloud-Init in the guest operating system of a virtual machine, the `postcustomization` section runs before the customization due to a known issue in Cloud-Init.

Workaround: Disable Cloud-Init and use the standard guest customization.

Group migration operations in vSphere vMotion, Storage vMotion, and vMotion without shared storage fail with error

When you perform group migration operations on VMs with multiple disks and multi-level snapshots, the operations might fail with the error `com.vmware.vc.GenericVmConfigFault Failed waiting for data. Error 195887167. Connection closed by remote host, possibly due to timeout.`

Workaround: Retry the migration operation on the failed VMs one at a time.

Deploying an OVF or OVA template from a URL fails with a 403 Forbidden error

The URLs that contain an HTTP query parameter are not supported. For example, `http://webaddress.com?file=abc.ovf` or the Amazon pre-signed S3 URLs.

Workaround: Download the files and deploy them from your local file system.

The third level of nested objects in a virtual machine folder is not visible

Perform the following steps:

1. Navigate to a data center and create a virtual machine folder.
2. In the virtual machine folder, create a nested virtual machine folder.
3. In the second folder, create another nested virtual machine, virtual machine folder, vApp, or VM Template.

As a result, from the VMs and Templates inventory tree you cannot see the objects in the third nested folder.

Workaround: To see the objects in the third nested folder, navigate to the second nested folder and select the VMs tab.

vSphere HA and Fault Tolerance Issues

VMs in a cluster might be orphaned after recovering from storage inaccessibility such as a cluster wide APD

Some VMs might be in orphaned state after cluster wide APD recovers, even if HA and VMCP are enabled on the cluster.

This issue might be encountered when the following conditions occur simultaneously:

- All hosts in the cluster experience APD and do not recover until VMCP timeout is reached.
- HA primary initiates failover due to APD on a host.
- Power on API during HA failover fails due to one of the following:
  - APD across the same host
  - Cascading APD across the entire cluster
  - Storage issues
  - Resource unavailability
- FDM unregistration and VCs steal VM logic might initiate during a window where FDM has not unregistered the failed VM and VC's host synchronization responds that multiple hosts are reporting the same VM. Both FDM and VC unregister the different registered copies of the same VM from different hosts, causing the VM to be orphaned.

Workaround: You must unregister and reregister the orphaned VMs manually within the cluster after the APD recovers.

If you do not manually reregister the orphaned VMs, HA attempts failover of the orphaned VMs, but it might take between 5 to 10 hours depending on when APD recovers.

The overall functionality of the cluster is not affected in these cases and HA will continue to protect the VMs. This is an anomaly in what gets displayed on VC for the duration of the problem.

vSphere Lifecycle Manager Issues

You cannot enable NSX-T on a cluster that is already enabled for managing image setup and updates on all hosts collectively

NSX-T is not compatible with the vSphere Lifecycle Manager functionality for image management. When you enable a cluster for image setup and updates on all hosts in the cluster collectively, you cannot enable NSX-T on that cluster. However, you can deploy NSX Edges to this cluster.

Workaround: Move the hosts to a new cluster that you can manage with baselines and enable NSX-T on that new cluster.

vSphere Lifecycle Manager and vSAN File Services cannot be simultaneously enabled on a vSAN cluster in vSphere 7.0 release

If vSphere Lifecycle Manager is enabled on a cluster, vSAN File Services cannot be enabled on the same cluster and vice versa. In order to enable vSphere Lifecycle Manager on a cluster, which has VSAN File Services enabled already, first disable vSAN File Services and retry the operation. Please note that if you transition to a cluster that is managed by a single image, vSphere Lifecycle Manager cannot be disabled on that cluster.

Workaround: None.

When a hardware support manager is unavailable, vSphere High Availability (HA) functionality is impacted

If hardware support manager is unavailable for a cluster that you manage with a single image, where a firmware and drivers addon is selected and vSphere HA is enabled, the vSphere HA functionality is impacted. You may experience the following errors.

- Configuring vSphere HA on a cluster fails.
- Cannot complete the configuration of the vSphere HA agent on a host: `Applying HA VIBs on the cluster encountered a failure.`
- Remediating vSphere HA fails: `A general system error occurred: Failed to get Effective Component map.`
- Disabling vSphere HA fails: Delete Solution task failed. `A general system error occurred: Cannot find hardware support package from depot or hardware support manager.`

Workaround:

- If the hardware support manager is temporarily unavailable, perform the following steps.

1. Reconnect the hardware support manager to vCenter Server.
2. Select a cluster from the Hosts and Cluster menu.
3. Select the Configure tab.
4. Under Services, click vSphere Availability.
5. Re-enable vSphere HA.

- If the hardware support manager is permanently unavailable, perform the following steps.

1. Remove the hardware support manager and the hardware support package from the image specification
2. Re-enable vSphere HA.
3. Select a cluster from the Hosts and Cluster menu.
4. Select the Updates tab.
5. Click Edit .
6. Remove the firmware and drivers addon and click Save.
7. Select the Configure tab.
8. Under Services, click vSphere Availability.
9. Re-enable vSphere HA.

I/OFilter is not removed from a cluster after a remediation process in vSphere Lifecycle Manager

Removing I/OFilter from a cluster by remediating the cluster in vSphere Lifecycle Manager, fails with the following error message: `iofilter XXX already exists` . The iofilter remains listed as installed.

Workaround:

1. Call IOFilter API `UninstallIoFilter_Task` from the vCenter Server managed object (IoFilterManager).
2. Remediate the cluster in vSphere Lifecycle Manager.
3. Call IOFilter API `ResolveInstallationErrorsOnCluster_Task` from the vCenter Server managed object (IoFilterManager) to update the database.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, adding hosts causes a vSphere HA error state

Adding one or multiple ESXi hosts during a remediation process of a vSphere HA enabled cluster, results in the following error message: `Applying HA VIBs on the cluster encountered a failure.`

Workaround: After the cluster remediation operation has finished, perform one of the following tasks.

- Right-click the failed ESXi host and select *Reconfigure for vSphere HA*.
- Disable and re-enable vSphere HA for the cluster.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, disabling and re-enabling vSphere HA causes a vSphere HA error state

Disabling and re-enabling vSphere HA during remediation process of a cluster, may fail the remediation process due to vSphere HA health checks reporting that hosts don't have vSphere HA VIBs installed. You may see the following error message: `Setting desired image spec for cluster failed.`

Workaround: After the cluster remediation operation has finished, disable and re-enable vSphere HA for the cluster.

Checking for recommended images in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the recommendation generation task could take more than an hour to finish or may appear to hang. The completion time for the recommendation task depends on the number of devices configured on each host and the number of image candidates from the depot that vSphere Lifecycle Manager needs to process before obtaining a valid image to recommend.

Workaround: None.

Checking for hardware compatibility in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the validation report generation task could take up to 30 minutes to finish or may appear to hang. The completion time depends on the number of devices configured on each host and the number of hosts configured in the cluster.

Workaround: None

Incomplete error messages in non-English languages are displayed, when remediating a cluster in vSphere Lifecycle Manager

You can encounter incomplete error messages for localized languages in the vCenter Server user interface. The messages are displayed, after a cluster remediation process in vSphere Lifecycle Manager fails. For example, your can observe the following error message.

The error message in English language: `Virtual machine 'VMC on DELL EMC -FileServer' that runs on cluster 'Cluster-1' reported an issue which prevents entering maintenance mode: Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

The error message in French language: `La VM « VMC on DELL EMC -FileServer », située sur le cluster « {Cluster-1} », a signalé un problème empêchant le passage en mode de maintenance : Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

Workaround: None.

Importing an image with no vendor addon, components, or firmware and drivers addon to a cluster which image contains such elements, does not remove the image elements of the existing image

Only the ESXi base image is replaced with the one from the imported image.

Workaround: After the import process finishes, edit the image, and if needed, remove the vendor addon, components, and firmware and drivers addon.

When you convert a cluster that uses baselines to a cluster that uses a single image, a warning is displayed that vSphere HA VIBs will be removed

Converting a vSphere HA enabled cluster that uses baselines to a cluster that uses a single image, may result a warning message displaying that `vmware-fdm` component will be removed.

Workaround: This message can be ignored. The conversion process installs the `vmware-fdm` component.

If vSphere Update Manager is configured to download patch updates from the Internet through a proxy server, after upgrade to vSphere 7.0 that converts Update Manager to vSphere Lifecycle Manager, downloading patches from VMware patch repository might fail

In earlier releases of vCenter Server you could configure independent proxy settings for vCenter Server and vSphere Update Manager. After an upgrade to vSphere 7.0, vSphere Update Manager service becomes part of the vSphere Lifecycle Manager service. For the vSphere Lifecycle Manager service, the proxy settings are configured from the vCenter Server appliance settings. If you had configured Update Manager to download patch updates from the Internet through a proxy server but the vCenter Server appliance had no proxy setting configuration, after a vCenter Server upgrade to version 7.0, the vSphere Lifecycle Manager fails to connect to the VMware depot and is unable to download patches or updates.

Workaround: Log in to the vCenter Server Appliance Management Interface, https://*vcenter-server-appliance-FQDN-or-IP-address*:5480, to configure proxy settings for the vCenter Server appliance and enable vSphere Lifecycle Manager to use proxy.

Miscellaneous Issues

When applying a host profile with version 6.5 to a ESXi host with version 7.0, the compliance check fails

Applying a host profile with version 6.5 to a ESXi host with version 7.0, results in Coredump file profile reported as not compliant with the host.

Workaround: There are two possible workarounds.

1. When you create a host profile with version 6.5, set an advanced configuration option VMkernel.Boot.autoCreateDumpFile to false on the ESXi host.
2. When you apply an existing host profile with version 6.5, add an advanced configuration option VMkernel.Boot.autoCreateDumpFile in the host profile, configure the option to a fixed policy, and set value to false.

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit minor throughput degradation when Dynamic Receive Side Scaling (DYN_RSS) or Generic RSS (GEN_RSS) feature is turned on

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit less than 5 percent throughput degradation when DYN_RSS and GEN_RSS feature is turned on, which is unlikely to impact normal workloads.

Workaround: You can disable DYN_RSS and GEN_RSS feature with the following commands:

```
# esxcli system module parameters set -m nmlx5_core -p "DYN_RSS=0 GEN_RSS=0"
# reboot
```

RDMA traffic between two VMs on the same host might fail in PVRDMA environment

In a vSphere 7.0 implementation of a PVRDMA environment, VMs pass traffic through the HCA for local communication if an HCA is present. However, loopback of RDMA traffic does not work on qedrntv driver. For instance, RDMA Queue Pairs running on VMs that are configured under same uplink port cannot communicate with each other.

In vSphere 6.7 and earlier, HCA was used for local RDMA traffic if SRQ was enabled. vSphere 7.0 uses HCA loopback with VMs using versions of PVRDMA that have SRQ enabled with a minimum of HW v14 using RoCE v2.

The current version of Marvell FastLinQ adapter firmware does not support loopback traffic between QPs of the same PF or port.

Workaround: Required support is being added in the out-of-box driver certified for vSphere 7.0. If you are using the inbox qedrntv driver, you must use a 3-host configuration and migrate VMs to the third host.

Unreliable Datagram traffic QP limitations in qedrntv driver

There are limitations with the Marvell FastLinQ qedrntv RoCE driver and Unreliable Datagram (UD) traffic. UD applications involving bulk traffic might fail with qedrntv driver. Additionally, UD QPs can only work with DMA Memory Regions (MR). Physical MRs or FRMR are not supported. Applications attempting to use physical MR or FRMR along with UD QP fail to pass traffic when used with qedrntv driver. Known examples of such test applications are `ibv_ud_pingpong` and `ib_send_bw`.

Standard RoCE and RoCEv2 use cases in a VMware ESXi environment such as iSER, NVMe-oF (RoCE) and PVRDMA are not impacted by this issue. Use cases for UD traffic are limited and this issue impacts a small set of applications requiring bulk UD traffic.

Marvell FastLinQ hardware does not support RDMA UD traffic offload. In order to meet the VMware PVRDMA requirement to support GSI QP, a restricted software only implementation of UD QP support was added to the qedrntv driver. The goal of the implementation is to provide support for control path GSI communication and is not a complete implementation of UD QP supporting bulk traffic and advanced features.

Since UD support is implemented in software, the implementation might not keep up with heavy traffic and packets might be dropped. This can result in failures with bulk UD traffic.

Workaround: Bulk UD QP traffic is not supported with qedrntv driver and there is no workaround at this time. VMware ESXi RDMA (RoCE) use cases like iSER, NVMe, RDMA and PVRDMA are unaffected by this issue.

Servers equipped with QLogic 578xx NIC might fail when frequently connecting or disconnecting iSCSI LUNs

If you trigger QLogic 578xx NIC iSCSI connection or disconnection frequently in a short time, the server might fail due to an issue with the qfle3 driver. This is caused by a known defect in the device's firmware.

Workaround: None.

ESXi might fail during driver unload or controller disconnect operation in Broadcom NVMe over FC environment

In Broadcom NVMe over FC environment, ESXi might fail during driver unload or controller disconnect operation and display an error message such as: `@BlueScreen: #PF Exception 14 in world 2098707:vmknvmeGener IP 0x4200225021cc addr 0x19`

Workaround: None.

ESXi does not display OEM firmware version number of i350/X550 NICs on some Dell servers

The inbox ixgben driver only recognizes firmware data version or signature for i350/X550 NICs. On some Dell servers the OEM firmware version number is programmed into the OEM package version region, and the inbox ixgben driver does not read this information. Only the 8-digit firmware signature is displayed.

Workaround: To display the OEM firmware version number, install async ixgben driver version 1.7.15 or later.

X710 or XL710 NICs might fail in ESXi

When you initiate certain destructive operations to X710 or XL710 NICs, such as resetting the NIC or manipulating VMKernel's internal device tree, the NIC hardware might read data from non-packet memory.

Workaround: Do not reset the NIC or manipulate vmkernel internal device state.

NVMe-oF does not guarantee persistent VMHBA name after system reboot

NVMe-oF is a new feature in vSphere 7.0. If your server has a USB storage installation that uses vmhba30+ and also has NVMe over RDMA configuration, the VMHBA name might change after a system reboot. This is because the VMHBA name assignment for NVMe over RDMA is different from PCIe devices. ESXi does not guarantee persistence.

Workaround: None.

Backup fails for vCenter database size of 300 GB or greater

If the vCenter database size is 300 GB or greater, the file-based backup will fail with a timeout. The following error message is displayed: `Timeout! Failed to complete in 72000 seconds`

Workaround: None.

A restore of vCenter Server 7.0 which is upgraded from vCenter Server 6.x with External Platform Services Controller to vCenter Server 7.0 might fail

When you restore a vCenter Server 7.0 which is upgraded from 6.x with External Platform Services Controller to vCenter Server 7.0, the restore might fail and display the following error: `Failed to retrieve appliance storage list`

Workaround: During the first stage of the restore process, increase the storage level of the vCenter Server 7.0. For example if the vCenter Server 6.7 External Platform Services Controller setup storage type is small, select storage type large for the restore process.

Enabled SSL protocols configuration parameter is not configured during a host profile remediation process

`Enabled SSL protocols` configuration parameter is not configured during a host profile remediation and only the system default protocol `tlsv1.2` is enabled. This behavior is observed for a host profile with version 7.0 and earlier in a vCenter Server 7.0 environment.

Workaround: To enable TLSV 1.0 or TLSV 1.1 SSL protocols for SFCB, log in to an ESXi host by using SSH, and run the following ESXCLI command: `esxcli system wbem -P <protocol_name>`

Unable to configure Lockdown Mode settings by using Host Profiles

Lockdown Mode cannot be configured by using a security host profile and cannot be applied to multiple ESXi hosts at once. You must manually configure each host.

Workaround: In vCenter Server 7.0, you can configure Lockdown Mode and manage Lockdown Mode exception user list by using a security host profile.

When a host profile is applied to a cluster, Enhanced vMotion Compatibility (EVC) settings are missing from the ESXi hosts

Some settings in the VMware config file `/etc/vmware/config` are not managed by Host Profiles and are blocked, when the config file is modified. As a result, when the host profile is applied to a cluster, the EVC settings are lost, which causes loss of EVC functionalities. For example, unmasked CPUs can be exposed to workloads.

Workaround: Reconfigure the relevant EVC baseline on cluster to recover the EVC settings.

Using a host profile that defines a core dump partition in vCenter Server 7.0 results in an error

In vCenter Server 7.0, configuring and managing a core dump partition in a host profile is not available. Attempting to apply a host profile that defines a core dump partition, results in the following error: `No valid coredump partition found.`

Workaround: None. In vCenter Server 7.0., Host Profiles supports only file-based core dumps.

If you run the ESXCLI command to unload the firewall module, the hostd service fails and ESXi hosts lose connectivity

If you automate the firewall configuration in an environment that includes multiple ESXi hosts, and run the ESXCLI command `esxcli network firewall unload` that destroys filters and unloads the firewall module, the hostd service fails and ESXi hosts lose connectivity.

Workaround: Unloading the firewall module is not recommended at any time. If you must unload the firewall module, use the following steps:

1. Stop the hostd service by using the command:
   `/etc/init.d/hostd stop.`
2. Unload the firewall module by using the command:
   `esxcli network firewall unload.`
3. Perform the required operations.
4. Load the firewall module by using the command:
   `esxcli network firewall load.`
5. Start the hostd service by using the command:
   `/etc/init.d/hostd start.`

vSphere Storage vMotion operations might fail in a vSAN environment due to an unauthenticated session of the Network File Copy (NFC) manager

Migrations to a vSAN datastore by using vSphere Storage vMotion of virtual machines that have at least one snapshot and more than one virtual disk with different storage policy might fail. The issue occurs due to an unauthenticated session of the NFC manager because the Simple Object Access Protocol (SOAP) body exceeds the allowed size.

Workaround: First migrate the VM home namespace and just one of the virtual disks. After the operation completes, perform a disk only migration of the remaining 2 disks.

Changes in the properties and attributes of the devices and storage on an ESXi host might not persist after a reboot

If the device discovery routine during a reboot of an ESXi host times out, the jumpstart plug-in might not receive all configuration changes of the devices and storage from all the registered devices on the host. As a result, the process might restore the properties of some devices or storage to the default values after the reboot.

Workaround: Manually restore the changes in the properties of the affected device or storage.

If you use a beta build of ESXi 7.0, ESXi hosts might fail with a purple diagnostic screen during some lifecycle operations

If you use a beta build of ESXi 7.0, ESXi hosts might fail with a purple diagnostic screen during some lifecycle operations such as unloading a driver or switching between ENS mode and native driver mode. For example, if you try to change the ENS mode, in the backtrace you see an error message similar to: `case ENS::INTERRUPT::NoVM_DeviceStateWithGracefulRemove hit BlueScreen: ASSERT bora/vmkernel/main/dlmalloc.c:2733` This issue is specific for beta builds and does not affect release builds such as ESXi 7.0.

Workaround: Update to ESXi 7.0 GA.

You cannot create snapshots of virtual machines due to an error that a digest operation has failed

A rare race condition when an All-Paths-Down (APD) state occurs during the update of the Content Based Read Cache (CBRC) digest file might cause inconsistencies in the digest file. As a result, you cannot create virtual machine snapshots. You see an error such as `An error occurred while saving the snapshot: A digest operation has failed` in the backtrace.

Workaround: Power cycle the virtual machines to trigger a recompute of the CBRC hashes and clear the inconsistencies in the digest file.

If you upgrade your ESXi hosts to version 7.0 Update 3, but your vCenter Server is of an earlier version, Trusted Platform Module (TPM) attestation of the ESXi hosts fails

If you upgrade your ESXi hosts to version 7.0 Update 3, but your vCenter Server is of an earlier version, and you enable TPM, ESXi hosts fail to pass attestation. In the vSphere Client, you see the warning Host TPM attestation alarm. The Elliptic Curve Digital Signature Algorithm (ECDSA) introduced with ESXi 7.0 Update 3 causes the issue when vCenter Server is not of version 7.0 Update 3.

Workaround: Upgrade your vCenter Server to 7.0 Update 3 or acknowledge the alarm.

You see warnings in the boot loader screen about TPM asset tags

If a TPM-enabled ESXi host has no asset tag set on, you might see idle warning messages in the boot loader screen such as:

```
Failed to determine TPM asset tag size: Buffer too smallFailed to measure asset tag into TPM: Buffer too small
```

Workaround: Ignore the warnings or set an asset tag by using the command `$ esxcli hardware tpm tag set -d`

The sensord daemon fails to report ESXi host hardware status

A logic error in the IPMI SDR validation might cause `sensord` to fail to identify a source for power supply information. As a result, when you run the command `vsish -e get /power/hostStats` , you might not see any output.

Workaround: None

If an ESXi host fails with a purple diagnostic screen, the netdump service might stop working

In rare cases, if an ESXi host fails with a purple diagnostic screen, the netdump service might fail with an error such as `NetDump FAILED: Couldn't attach to dump server at IP x.x.x.x.`

Workaround: Configure the VMkernel core dump to use local storage.

You see frequent VMware Fault Domain Manager (FDM) core dumps on multiple ESXi hosts

In some environments, the number of datastores might exceed the FDM file descriptor limit. As a result, you see frequent core dumps on multiple ESXi hosts indicating FDM failure.

Workaround: Increase the FDM file descriptor limit to 2048. You can use the setting `das.config.fdm.maxFds` from the vSphere HA advanced options in the vSphere Client. For more information, see Set Advanced Options.

Virtual machines on a vSAN cluster with enabled NSX-T and a converged vSphere Distributed Switch (CVDS) in a VLAN transport zone cannot power on after a power off

If a secondary site is 95% disk full and VMs are powered off before simulating a secondary site failure, during recovery some of the virtual machines fail to power on. As a result, virtual machines become unresponsive. The issue occurs regardless if site recovery includes adding disks or ESXi hosts or CPU capacity.

Workaround: Select the virtual machines that do not power on and change the network to VM Network from Edit Settings on the VM context menu.

ESXI hosts might fail with a purple diagnostic screen with an error Assert at bora/modules/vmkernel/vmfs/fs6Journal.c:835

In rare cases, for example when running SESparse tests, the number of locks per transaction in a VMFS datastore might exceed the limit of 50 for the `J6_MAX_TXN_LOCKACTIONS` parameter. As a result, ESXi hosts might fail with a purple diagnostic screen with an error `Assert at bora/modules/vmkernel/vmfs/fs6Journal.c:835` .

Workaround: None

If you modify the netq_rss_ens parameter of the nmlx5_core driver, ESXi hosts might fail with a purple diagnostic screen

If you try to enable the `netq_rss_ens` parameter when you configure an enhanced data path on the `nmlx5_core` driver, ESXi hosts might fail with a purple diagnostic screen. The `netq_rss_ens` parameter, which enables NetQ RSS, is disabled by default with a value of `0` .

Workaround: Keep the default value for the `netq_rss_ens` module parameter in the `nmlx5_core` driver.

ESXi might terminate I/O to NVMeOF devices due to errors on all active paths

Occasionally, all active paths to NVMeOF device register I/O errors due to link issues or controller state. If the status of one of the paths changes to Dead, the High Performance Plug-in (HPP) might not select another path if it shows high volume of errors. As a result, the I/O fails.

Workaround: Disable the configuration option **/Misc/HppManageDegradedPaths** to unblock the I/O.

Upgrade to ESXi 7.0 Update 3 might fail due to changed name of the inbox i40enu network driver

Starting with vSphere 7.0 Update 3, the inbox i40enu network driver for ESXi changes name back to i40en. The i40en driver was renamed to i40enu in vSphere 7.0 Update 2, but the name change impacted some upgrade paths. For example, rollup upgrade of ESXi hosts that you manage with baselines and baseline groups from 7.0 Update 2 or 7.0 Update 2a to 7.0 Update 3 fails. In most cases, the i40enu driver upgrades to ESXi 7.0 Update 3 without any additional steps. However, if the driver upgrade fails, you cannot update ESXi hosts that you manage with baselines and baseline groups. You also cannot use host seeding or a vSphere Lifecycle Manager single image to manage the ESXi hosts. If you have already made changes related to the i40enu driver and devices in your system, before upgrading to ESXi 7.0 Update 3, you must uninstall the i40enu VIB or Component on ESXi, or first upgrade ESXi to ESXi 7.0 Update 2c.

Workaround: For more information, see VMware knowledge base article 85982.

SSH access fails after you upgrade to ESXi 7.0 Update 3d

After you upgrade to ESXi 7.0 Update 3d, SSH access might fail in certain conditions due to an update of OpenSSH to version 8.8.

Workaround: For more information, see VMware knowledge base article 88055.

USB device passthrough from ESXi hosts to virtual machines might fail

A USB modem device might simultaneously claim multiple interfaces by the VMkernel and block the device passthrough to VMs.

Workaround: You must apply the USB.quirks advanced configuration on the ESXi host to ignore the NET interface from VMkernel and allow the USB modem to passthrough to VMs. You can apply the configuration in 3 alternative ways:

1. Access the ESXi shell and run the following command: `esxcli system settings advanced set -o /USB/quirks -s 0xvvvv:0xpppp:0:0xffff:UQ_NET_IGNORE | |- Device Product ID |------- Device Vendor ID`
   For example, for the Gemalto M2M GmbH Zoom 4625 Modem(`vid:pid/1e2d:005b`), you can have the command `esxcli system settings advanced set` **-o** `/USB/quirks -s 0x1e2d:0x005b:0:0xffff:UQ_NET_IGNORE`
   Reboot the ESXi host.
2. Set the advanced configuration from the vSphere Client or the vSphere Web Client and reboot the ESXi host.
3. Use a Host Profile to apply the advanced configuration.

For more information on the steps, see VMware knowledge base article 80416.

HTTP requests from certain libraries to vSphere might be rejected

The HTTP reverse proxy in vSphere 7.0 enforces stricter standard compliance than in previous releases. This might expose pre-existing problems in some third-party libraries used by applications for SOAP calls to vSphere.

If you develop vSphere applications that use such libraries or include applications that rely on such libraries in your vSphere stack, you might experience connection issues when these libraries send HTTP requests to VMOMI. For example, HTTP requests issued from vijava libraries can take the following form:

```
POST /sdk HTTP/1.1
SOAPAction
Content-Type: text/xml; charset=utf-8
User-Agent: Java/1.8.0_221
```

The syntax in this example violates an HTTP protocol header field requirement that mandates a colon after SOAPAction. Hence, the request is rejected in flight.

Workaround: Developers leveraging noncompliant libraries in their applications can consider using a library that follows HTTP standards instead. For example, developers who use the vijava library can consider using the latest version of the yavijava library instead.

You might see a dump file when using Broadcom driver lsi_msgpt3, lsi_msgpt35 and lsi_mr3

When using the lsi_msgpt3, lsi_msgpt35 and lsi_mr3 controllers, there is a potential risk to see dump file lsuv2-lsi-drivers-plugin-util-zdump. There is an issue when exiting the storelib used in this plugin utility. There is no impact on ESXi operations, you can ignore the dump file.

Workaround: You can safely ignore this message. You can remove the lsuv2-lsi-drivers-plugin with the following command:

```
esxcli software vib remove -n lsuv2-lsiv2-drivers-plugin
```

You might see reboot is not required after configuring SR-IOV of a PCI device in vCenter, but device configurations made by third party extensions might be lost and require reboot to be re-applied.

In ESXi 7.0, SR-IOV configuration is applied without a reboot and the device driver is reloaded. ESXi hosts might have third party extensions perform device configurations that need to run after the device driver is loaded during boot. A reboot is required for those third party extensions to re-apply the device configuration.

Workaround: You must reboot after configuring SR-IOV to apply third party device configurations.

vSphere Client Issues

BIOS manufacturer displays as "--" in the vSphere Client

In the vSphere Client, when you select an ESXi host and navigate to **Configure** > **Hardware** > **Firmware**, you see `--` instead of the BIOS manufacturer name.

Workaround: For more information, see VMware knowledge base article 88937.

VMware ESXi 7.0 Update 3l Release Notes

This document contains the following sections

- Introduction
- What's New
- Earlier Releases of ESXi 7.0
- Patches Contained in This Release
- Patch Download and Installation

- Product Support Notices
- Resolved Issues
- Known Issues
- Known Issues from Previous Releases

Introduction

ESXi 7.0 Update 3l | MAR 30 2023 | ISO Build 21424296
Check for additions and updates to these release notes.

IMPORTANT: If your source system contains hosts of versions between ESXi 7.0 Update 2 and Update 3c, and Intel drivers, before upgrading to ESXi 7.0 Update 3l, see the What's New section of the VMware vCenter Server 7.0 Update 3c Release Notes, because all content in the section is also applicable for vSphere 7.0 Update 3l. Also, see the related VMware knowledge base articles: 86447, 87258, and 87308.

What's New

- ESXi 7.0 Update 3l supports vSphere Quick Boot on the following servers:
  - Cisco
    - UCSC-C225-M6S
  - Dell
    - R660 vSAN Ready Node
    - R760 vSAN Ready Node
    - PowerEdge R660xs
    - PowerEdge R760xa
    - PowerEdge R760xd2
    - PowerEdge R760xs
    - PowerEdge R860
    - PowerEdge R960
    - PowerEdge T560
  - HPE
    - Alletra 4120
    - Cray XD220v
    - ProLiant DL320 Gen11
    - ProLiant DL380a Gen11
    - ProLiant DL560 Gen11
    - ProLiant ML110 Gen11
- This release resolves CVE-2023-1017. VMware has evaluated the severity of this issue to be in the low severity range with a maximum CVSSv3 base score of 3.3.
- This release resolves CVE-2023-1018. VMware has evaluated the severity of this issue to be in the low severity range with a maximum CVSSv3 base score of 3.3.

Earlier Releases of ESXi 7.0

New features, resolved, and known issues of ESXi are described in the release notes for each release. Release notes for earlier releases of ESXi 7.0 are:

- VMware ESXi 7.0, ESXi 7.0 Update 3k Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3j Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3i Release Notes

- VMware ESXi 7.0, ESXi 7.0 Update 3g Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3f Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1e Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 3c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2a Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 2 Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1d Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1c Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1b Release Notes
- VMware ESXi 7.0, ESXi 7.0 Update 1a Release Notes

Patches Contained in This Release

This release of ESXi 7.0 Update 3l delivers the following patches:

Build Details

Download Filename:	VMware-ESXi-7.0U3l-21424296-depot
Build:	21424296
Download Size:	570.6 MB
md5sum:	bc8be7994ff95cf45e218f19eb38a4f1
sha256checksum:	a85acc0fab15d5c2744e6b697817961fde3979eddfc4dd1af07c83731f2f87cf
Host Reboot Required:	Yes
Virtual Machine Migration or Shutdown Required:	Yes

Components

Component	Bulletin	Category	Severity
ESXi Component - core ESXi VIBs	ESXi_7.0.3-0.85.21424296	Bugfix	Critical
ESXi Install/Upgrade Component	esx-update_7.0.3-0.85.21424296	Bugfix	Critical
Broadcom NetXtreme I ESX VMKAPI ethernet driver	Broadcom-ntg3_4.1.9.0-4vmw.703.0.85.21424296	Bugfix	Critical
Non-Volatile memory controller driver	VMware-NVMe-PCIe_1.2.3.16-2vmw.703.0.85.21424296	Bugfix	Critical
USB Native Driver for VMware	VMware-vmkusb_0.1-8vmw.703.0.85.21424296	Bugfix	Critical

Component	Bulletin	Category	Severity
ESXi Component - core ESXi VIBs	ESXi_7.0.3-0.80.21422485	Security	Critical
ESXi Install/Upgrade Component	esx-update_7.0.3-0.80.21422485	Security	Critical
ESXi Tools Component	VMware-VM-Tools_12.1.5.20735119-21422485	Security	Critical

IMPORTANT:

- Starting with vSphere 7.0, VMware uses components for packaging VIBs along with bulletins. The `ESXi` and `esx-update` bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.
- When patching ESXi hosts by using VMware Update Manager from a version prior to ESXi 7.0 Update 2, it is strongly recommended to use the rollup bulletin in the patch baseline. If you cannot use the rollup bulletin, be sure to include *all* of the following packages in the patching baseline. If the following packages are not included in the baseline, the update operation fails:
  - VMware-vmkusb_0.1-1vmw.701.0.0.16850804 or higher
  - VMware-vmkata_0.1-1vmw.701.0.0.16850804 or higher
  - VMware-vmkfcoe_1.0.0.2-1vmw.701.0.0.16850804 or higher
  - VMware-NVMeoF-RDMA_1.0.1.2-1vmw.701.0.0.16850804 or higher

Rollup Bulletin

This rollup bulletin contains the latest VIBs with all the fixes after the initial release of ESXi 7.0.

Bulletin ID	Category	Severity	Details
ESXi70U3l-21424296	Bugfix	Critical	Security and Bugfix
ESXi70U3sl-21422485	Security	Critical	Security only

Image Profiles

VMware patch and update releases contain general and critical image profiles. Application of the general release image profile applies to new bug fixes.

Image Profile Name
ESXi-7.0U3l-21424296-standard
ESXi-7.0U3l-21424296-no-tools
ESXi-7.0U3sl-21422485-standard
ESXi-7.0U3sl-21422485-no-tools

ESXi Image

Name and Version	Release Date	Category	Detail
ESXi7.0U3l - 21424296	MAR 30 2023	Bugfix	Security and Bugfix image
ESXi7.0U3sl - 21422485	MAR 30 2023	Security	Security only image

Patch Download and Installation

Log in to the Broadcom Support Portal to download this patch.

For download instructions for earlier releases, see Download Broadcom products and software.

In vSphere 7.x, the Update Manager plug-in, used for administering vSphere Update Manager, is replaced with the Lifecycle Manager plug-in. Administrative operations for vSphere Update Manager are still available under the Lifecycle Manager plug-in, along with new capabilities for vSphere Lifecycle Manager.

The typical way to apply patches to ESXi 7.x hosts is by using the vSphere Lifecycle Manager. For details, see About vSphere Lifecycle Manager and vSphere Lifecycle Manager Baselines and Images.

You can also update ESXi hosts without using the Lifecycle Manager plug-in, and use an image profile instead. To do this, you must manually download the patch offline bundle ZIP file.

For details, see Upgrading Hosts by Using ESXCLI Commands, and the VMware ESXi Upgrade guide.

Product Support Notices

- **Restoring Memory Snapshots of a VM with independent disk for virtual machine backups is not supported**: You can take a memory snapshot of a virtual machine with an independent disk only to analyze the guest operating system behavior of a virtual machine. You cannot use such snapshots for virtual machine backups because restoring this type of snapshots is unsupported. You can convert a memory snapshot to a powered-off snapshot, which can be successfully restored.

Resolved Issues

The resolved issues are grouped as follows.

- ESXi_7.0.3-0.85.21424296
- esx-update_7.0.3-0.85.21424296
- Broadcom-ntg3_4.1.9.0-4vmw.703.0.85.21424296
- VMware-vmkusb_0.1-8vmw.703.0.85.21424296

CVE numbers	CVE-2023-1017, CVE-2023-1018

The ESXi and esx-update bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.

Updates the `esx-dvfilter-generic-fastpath`, `vsan`, `bmcal`, `crx`, `esx-ui`, `esxio-combiner`, `vsanhealth`, `native-misc-drivers`, `gc`, `cpu-microcode`, `vdfs`, `esx-xserver`, `esx-base`, and `trx` VIBs to resolve the following issues:

- **PR 3057026: When you change the NUMA nodes Per Socket (NPS) setting on an AMD EPYC 9004 'Genoa' server from the default of 1, you might see incorrect number of sockets**
  In the vSphere Client and the ESXi Host Client, you might see incorrect number of sockets and respectively cores per socket when you change the NPS setting on an AMD EPYC 9004 server from the default of 1, or Auto, to another value, such as 2 or 4.
  This issue is resolved in this release.
- **PR 3062185: ESXi hosts might fail with a purple diagnostic screen during a vSphere Storage vMotion operation or hot-adding a device**
  Due to a rare race condition during a Fast Suspend Resume (FSR) operation on a VM with shared pages between VMs, ESXi hosts might fail with a purple diagnostic screen with an error such as **PFrame_IsBackedByLPage** in the backtrace. The issue occurs during vSphere Storage vMotion operations or hot-adding a device.
  This issue is resolved in this release.
- **PR 3040049: The performance of the pktcap-uw utility degrades when using the -c option for counting packets in heavy network traffic**
  Packet capture with the **-c** option of the **pktcap-uw** utlity in heavy network traffic might be slower than packet capture without the option. You might also see a delay in capturing packets, so that the last package counted has a timestap few seconds earlier than the stop time of the function. The issue results from the **File_GetSize** function to check file sizes, which is slow in VMFS environments and causes low performance of **pktcap-uw**.
  This issue is resolved in this release. The fix changes the **File_GetSize** function with the **lseek** function to enhance performance.

- **PR 3061156: The Data Center Bridging (DCB) daemon on an ESXi host might generate a log spew in the syslog**
  In the **syslog** file you might see frequent log messages such as:
  2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info] * Received pre-CEE DCBX Packet on port: vmnicX**
  2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info]2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info] Src MAC: xc:xc:X0:0X:xc:xx
  2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info] Dest MAC: X0:xb:xb:fx:0X:X1
  2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info] 2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info] Port ID TLV:
  2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info] ifName:
  The issue occurs because the Data Center Bridging (DCB) daemon, **dcbd**, on the ESXi host records unnecessary messages at **/var/log/syslog.log**. As a result, the log file might quickly fill up with **dcbd** logs.
  This issue is resolved in this release.
- **PR 3023389: You see up to 100% CPU usage on one of the cores of an ESXi host due to an early timed-wait system call**
  In some cases, a timed-wait system call in the VMkernel might return too early. As a result, some applications, such as the System Health Agent, might take up to 100% of the CPU usage on one of the ESXi host cores.
  This issue is resolved in this release.
- **PR 3062861: You do not see virtual machine image details in the Summary tab of the vSphere Client**
  Due to an issue with the IPv6 loopback interfaces, you might not see virtual machine image details in the **Summary** tab of the vSphere Client.
  This issue is resolved in this release.
- **PR 3089449: If the number of paths from an ESXi host using SATP ALUA to storage exceeds 255, you might see I/O latency in some VMs**
  If the number of paths from an ESXi host using NMP SATP ALUA to storage exceed 255, ESXi ignores part of the ALUA information reported by the target and incorrectly retains some of the path state as active optimised. As a result, some I/Os use the non-optimised path to the storage device and cause latency issues..
  This issue is resolved in this release. The fix makes sure that when RTPG response length is greater than pre-allocated buffer length, ESXi reallocates RTPG buffer with the required size and re-issues the RTPG command.
- **PR 3081870: ESXi host reboot process stops with “initializing init_VMKernelShutdownHelper: (14/39) ShutdownSCSICleanupForDevTearDown” message**
  In some cases, during an ESXi host shutdown, helper queues of device probe requests get deleted, but the reference to the device remains. As a result, the ESXi host reboot stops with a message such as **initializing init_VMKernelShutdownHelper: (14/39) ShutdownSCSICleanupForDevTearDown** in the Direct Console User Interface (DCUI).
  This issue is resolved in this release. The fix adds a cancel function associated with helper requests that decrement device references when deleting helper queue requests.
- **PR 3082900: ESXi hosts might fail with a purple diagnostic screen during a VM Instant Clone operation**
  Due to a race condition during an Instant Clone operation, VM memory pages might be corrupted and the ESXi host might fail with a purple diagnostic screen. You see errors such as **VmMemMigrate_MarkPagesCow** or **AsyncRemapProcessVMRemapList** in the backtrace.
  This issue is resolved in this release.
- **PR 3033157: Storage failover might take long as repeated scans may be required to bring all paths to a LUN online**
  In some environments with SATP plug-ins such as **satp_alua** and **satp_alua_cx**, bringing all paths to a LUN online might require several scans. As a result, a storage failover operation might take long. For example, with 4 paths to a LUN, it might take up to 20 minutes to bring the 4 paths online.
  This issue is resolved in this release.

- **PR 3090683: Virtual machine vSphere tags might be lost after vSphere vMotion operations across vCenter Server instances**
  After vSphere vMotion operations across vCenter Server instances for VMs that have vSphere tags, it is possible that the tags do not exist in the target location. The issue only occurs in migration operations between vCenter Server instances that do not share storage.
  This issue is resolved in this release.
- **PR 3075786: The multicast filter mode of an NSX Virtual Switch might intermittently revert from legacy to snooping**
  When you set the multicast filter mode of an NSX Virtual Switch for NVDS, the mode might intermittently revert from legacy to snooping.
  This issue is resolved in this release. If you already face the issue, clear the stale property on the NVDS by completing the following steps:
  a. Run the **net-dvs** command on the ESXi host and check if **com.vmware.etherswitch.multicastFilter** is set on the NVDS. If **com.vmware.etherswitch.multicastFilter** is not set, no additional steps are required.
  b. If the property **com.vmware.etherswitch.multicastFilter** is set, use the following command to clear it:
  net-dvs -u com.vmware.etherswitch.multicastFilter -p globalPropList <NVDS name>
- **PR 3074392: IOFilterVP service stops when you run a Nessus scan on an ESXi host**
  When you run a Nessus scan, which internally runs a SYN scan, to detect active ports on an ESXi host, the iofiltervpd service might shut down. The service cannot be restarted within the max retry attempts due to the SYN scan.
  This issue is resolved in this release. The fix makes sure the IOFilterVP service handles the possible connection failure due to SYN scans.
- **PR 3081275: You see no change in the ESXi config after you run a restore config procedure and the ESXi host reboots**
  If a VIB containing a new kernel module is installed before you run any of the restore config procedures described in VMware knowledge base article 2042141, you see no change in the config after the ESXi host reboots. For example, if you attempt to restore the ESXi config immediately after installing the NSX VIB, the ESXi host reboots, but no changes in the config are visible. The issue occurs due to a logical fault in the updates of the bootbank partition used for ESXi host reboots after a new kernel module VIB is installed.
  This issue is resolved in this release.
- **PR 3080022: Listing files on mounted NFS 4.1 Azure storage might not work as expected**
  Listing files of mounted NFS 4.1 Azure storage might not work as expected, because although the files exist and you can open them by name, the **ls** command on an ESXi host by using SSH does not show any files.
  This issue is resolved in this release.
- **PR 3083314: Network File Copy (NFC) properties in the vpxa.cfg file might cause an ESXi host to fail with a purple diagnostic screen during upgrade**
  Starting with ESXi 7.0 Update 1, the **vpxa.cfg** file no longer exists and the vpxa configuration belongs to the ESXi Configuration Store (**ConfigStore**). When you upgrade an ESXi host from a version earlier than 7.0 Update 1 to a later version, the fields **Vpx.Vpxa.config.nfc.loglevel** and **Vpx.Vpxa.config.httpNfc.accessMode** in the **vpxa.cfg** file might cause the ESXi host to fail with a purple diagnostic screen during the conversion from **vpxa.cfg** format to **ConfigStore** format. The issue occurs due to discrepancies in the NFC log level between **vpxa.cfg** and **ConfigStore**, and case-sensitive values.
  This issue is resolved in this release. The fix removes the strict case-sensitive rules and maps NFC log level with their **ConfigStore** equivalents. For more information, see VMware knowledge base article 90865.
- **PR 3084812: Virtual machines might take longer to respond or become temporary unresponsive when vSphere DRS triggers multiple migration operations**
  In rare cases, multiple concurrent open and close operations on datastores, for example when vSphere DRS triggers multiple migration tasks, might cause some VMs to take longer to complete in-flight disk I/Os. As a result, such virtual machines might take longer to respond or become unresponsive for a short time. The issue is more likely to occur on VMs that have multiple virtual disks over different datastores.
  This issue is resolved in this release.

- **PR 3074360: After an API call to reload a virtual machine, the VM virtual NIC might disconnect from a Logical Switch Port (LSP)**
  During an API call to reload a virtual machine from one ESXi host to another, the **externalId** in the VM port data file might be lost. As a result, after the VM reloads, the VM virtual NIC might not be able to connect to a LSP.
  This issue is resolved in this release.
- **PR 3092270: VMware Host Client fails to attach an existing virtual disk to a virtual machine**
  After upgrading to ESXi 7.0 Update 3i, you might not be able to attach an existing virtual machine disk (VMDK) to a VM by using the VMware Host Client, which is used to connect to and manage single ESXi hosts. The issue does not affect the vSphere Client.
  This issue is resolved in this release.
- **PR 3076977: ESXi host might fail with a purple diagnostic screen due to a rare issue with dereferencing a freed pointer**
  Due to a race condition between the Create and Delete resource pool workflows, a freed pointer in the VMFS resource pool cache might get dereferenced. As a result, ESXi hosts might fail with a purple diagnostic screen and error such as:
  @BlueScreen: #PF Exception 14 in world 2105491:res3HelperQu IP 0x420032a21f55 addr 0x0
  This issue is resolved in this release.
- **PR 3051685: The batch QueryUnresolvedVmfsVolume API might take long to list a large number of unresolved VMFS volumes**
  With the batch **QueryUnresolvedVmfsVolume** API, you can query and list unresolved VMFS volumes or LUN snapshots. You can then use other batch APIs to perform operations, such as re-signaturing specific unresolved VMFS volumes. By default, when the API **QueryUnresolvedVmfsVolume** is invoked on a host, the system performs an additional filesystem liveness check for all unresolved volumes that are found. The liveness check detects whether the specified LUN is mounted on other hosts, whether an active VMFS heartbeat is in progress, or if there is any filesystem activity. This operation is time consuming and requires at least 16 seconds per LUN. As a result, when your environment has a large number of snapshot LUNs, the query and listing operation might take significant time.
  This issue is resolved in this release.
- **PR 3082477: vSAN cluster shutdown fails with error: 'NoneType' object has no attribute '_mold'**
  This problem can occur when vCenter manages multiple clusters, and the vCenter VM runs on one of the clusters. If you shut down the cluster where the vCenter VM resides, the following error can occur during the shutdown operation: **'NoneType' object has no attribute '_mold'**. The vCenter VM is not powered off.
  This issue is resolved in this release.
- **PR 3082282: You do not see the Restart Cluster option in the vSphere Client after shutting down multiple vSAN clusters**
  This problem can occur when vCenter manages multiple clusters and runs several shut down and restart cluster operations in parallel. For example, if you shut down 3 clusters and restart the vSAN health service or the vCenter VM, and you restart one of the 3 clusters before the others, the **Restart Cluster** option might be available for the first vSAN cluster, but not for the other clusters.
  This issue is resolved in this release.
- **PR 3082427: You see an unexpected time drift alert on vSAN clusters managed by the same vCenter Server**
  Unexpected time drift can occur intermittently on a vSAN cluster when a single vCenter Server manages several vSAN clusters, due to internal delays in VPXA requests. In the vSphere Client, in the vSAN Health tab, you see the status of **Time is synchronized across hosts and VC** changing from green to yellow and back to green.
  This issue is resolved in this release.
- **PR 3077163: When the ToolsRamdisk advanced option is active on an ESXi host, after a VM Tools upgrade, new versions are not available for VMs**
  When you enable the **ToolsRamdisk** advanced option that makes sure the **/vmtools** partition is always on a RAM disk rather than on a USB or SD-card, installing or updating the **tools-light** VIB does not update the content of the RAM

disk automatically. Instead, you must reboot the host so that the RAM disk updates and the new VM Tools version is available for the VMs.

This issue is resolved in this release. The fix makes sure that when **ToolsRamdisk** is enabled, VM Tools updates automatically, without the need of manual steps or restart.

- **PR 3087219: ESXi hosts might fail with a purple diagnostic screen after a migration operation**

  A rare race condition caused by memory reclamation for some performance optimization processes in vSphere vMotion might cause ESXi hosts to fail with a purple diagnostic screen.

  This issue is resolved in this release.
- **PR 3074187: ESXi hosts randomly fail with a purple diagnostic screen and an error such as Exception 14 in world #######**

  If your environment has both small and large file block clusters mapped to one affinity rule, when you add a cluster, the Affinity Manager might allocate more blocks for files than the actual volume of the datastore. As a result, ESXi hosts randomly fail with a purple diagnostic screen with error **Exception 14 in world #######**.

  This issue is resolved in this release.
- **PR 3082431: vSAN health history has no data available for the selected time period**

  This issue occurs when you view health details of any health check in the history view. In the vSphere Client, in the Skyline Health tab, you see a message such as **No data available for the selected time period**. The issue occurs when a query to the historical health records fails due to timestamps with an incorrect time zone.

  This issue is resolved in this release.
- **PR 3050562: You might see incorrect facility and severity values in ESXi syslog log messages**

  The logger command of some logger clients might not pass the right facility code to the ESXi syslog daemon and cause incorrect facility or severity values in ESXi syslog log messages.

  This issue is resolved in this release.
- **PR 3072430: A rare race condition in the Logical Volume Manager (LVM) schedule queue might cause an ESXi host to fail with a purple diagnostic screen**

  In rare cases, in a heavy workload, two LVM tasks that perform updating and querying on the device schedule in an ESXi host might run in parallel and cause a synchronization issue. As a result, the ESXi host might fail with a purple diagnostic screen and a messages similar to **LVMIoctlInt@com.vmware.lvm.ut#nover+0x1018 stack: 0xXXXXX and Addr3ResolvePhysVector@esx#nover+0x68 stack: 0xXXXX** in the backtrace.

  This issue is resolved in this release.
- **PR 3077072: When an ESXi host boots, some dynamically discovered iSCSI target portals and iSCSI LUNs might get deleted**

  In some cases, while an ESXi host boots, some dynamically discovered iSCSI targets might get deleted. As a result, after the boot completes, you might no longer see some iSCSI LUNs. The issue is more likely to occur in environments with Challenge-Handshake Authentication Protocol

  (CHAP) enabled for iSCSI.

  This issue is resolved in this release.
- **PR 3077060: The VMware Host Client or vSphere Client intermittently stop displaying software iSCSI adapters**

  In busy environments with many rescans by using a software iSCSI adapter, the VMware Host Client might intermittently stop displaying the adapter. The issue occurs only with target arrays which return target portals with both IPv4 and IPv6 addresses during discovery by using the **SendTargets** method.

  This issue is resolved in this release.
- **PR 3046875: Disabling Storage I/O Control on datastores results in high read I/O on all ESXi hosts**

  A rare issue with calculating the Max Queue Depth per datastore device might cause queue depth mismatch warnings from the underlying SCSI layer. As a result, when you disable Storage I/O Control on datastores, you might see high read I/O on all ESXi hosts.

  This issue is resolved in this release.

- **PR 3082991: After an upgrade to ESXi 7.0 Update 3 and later, you might see multiple -1.log files to fill up the root directory**
  Due to missing configuration for **stats-log** in the file **/etc/vmware/vvold/config.xml**, you might see multiple **-1.log** files to fill up the **/ramdisk** partition after an upgrade to ESXi 7.0 Update 3 and later.
  This issue is resolved in this release.
- **PR 3083473: Username or password in proxy cannot include an escape character**
  If a username or password in a network proxy contains any escape character, the environment fails to send network requests through the proxy.
  This issue is resolved in this release. The fix makes sure username or password work fine even with non-escaped characters.
- **PR 3051059: The command esxcli system ntp test fails to resolve the IP of an NTP server configured with additional parameters along with the host name**
  If you configure an NTP server on an ESXi host with additional parameters along with **hostname**, such as **min_poll** or **max_poll**, the command **esxcli system ntp test** might fail to resolve the IP address of that server. This issue occurs because in such configurations, the NTP name resolution applies to the entire server config instead of just the host name.
  This issue is resolved in this release.
- **PR 3091256: After upgrade to ESXi 7.0 Update 2 and later, VMs might not be able to communicate properly with some USB devices attached to the VMs**
  After upgrading to ESXi 7.0 Update 2 and later, a virtual machine might not discover some USB devices attached to it, such as an Eaton USB UPS, and fail to communicate with the device properly.
  This issue is resolved in this release.
- **PR 3074912: If you change the datastore of a cloned virtual machine before the initial power on, guest OS customizations might be lost**
  If you clone a VM, including the guest customization specs, move the VMDK file to another datastore and make it thick provisioned, and then power on the VM, the guest OS customization might not be preserved. In the hostd logs, you see an Event Type Description such as **The customization component failed to set the required parameters inside the guest operating system**.
  The issue occurs because while moving the VMDK file of the cloned VM to another datastore, the new **pathName** for the guest OS customization might temporarily be the same as the **oldPathName** and the package gets deleted.
  This issue is resolved in this release.
- **PR 3058993: Virtual machine-related tasks might fail when you use vSphere APIs for I/O Filtering (VAIO) for VMware or third-party backup applications**
  Improper sizing of the resource needs for the hostd service on an ESXi host might cause some virtual machine-related tasks to fail when you use vSphere APIs for I/O Filtering (VAIO) for VMware or third-party backup applications. For example, when a VAIO filter is attached to one or more virtual disks of a virtual machine, such VMs might fail to perform backups or power-on after a backup.
  This issue is resolved in this release. The fix increases the number of threads to prevent I/O-related issues with the hostd resources on ESXi hosts.
- **PR 3063987: First Class Disk (FCD) sync might fail on NFSv3 datastores and you see inconsistent values in Govc reports**
  A rare file corruption issue might occur when multiple ESXi hosts do a simultaneous file append operation on an NFSv3 datastore. As a result, if you use the Govc open source command-line utility to perform administrative actions on a vCenter instance, you might see reports with inconsistent values. For example, if you run the command **govc disk.ls** to list all FCDs in a newly created datastore, you see a different number of disks from what you expect.
  This issue is resolved in this release.
- **PR 3072500: ESXi hosts intermittently fail with a purple diagnostic screen and an error VERIFY bora/vmkernel/sched/cpusched.c**
  In rare cases, when a VMFS volume is closed immediately after it is opened, one of the threads in the opening process might race with a thread in the closing process and take a rare error handling path that can exit without unlocking a

locked spinlock. As a result, the ESXi host might fail with a purple diagnostic screen with a message in the backtrace such as: **@BlueScreen: VERIFY bora/vmkernel/sched/cpusched.c:11154.**

This issue is resolved in this release.

- **PR 3060661: Windows Server Failover Cluster (WSFC) applications might lose connectivity to a virtual volume-based disk after initiating a rebind operation on that disk**

  Due to reservation conflicts, WSFC applications might lose connectivity to a virtual volume-based disk after a rebind operation on that disk.

  This issue is resolved in this release.
- **PR 3076188: vSphere HA might not work as expected on a vSAN datastore after a power outage**

  In rare situations, the management agent that vSphere HA deploys on ESXi hosts, Fault Domain Manager (FDM), might fail to acquire a vSAN datastore in the first attempt before an exceptional condition, such as power outage, occurs. As a result, vSphere HA failover for virtual machines on that datastore might not be successful. In the vSphere Client, you see a message such as **This virtual machine failed to become vSphere HA Protected and HA may not attempt to restart it after a failure**. Successive attempts of FDM to acquire the vSAN datastore might also fail.

  This issue is resolved in this release. The fix makes sure that the successive attempts to acquire a vSAN datastore after an exceptional condition succeed.
- **PR 3049652: The Power|Total Energy (Wh) metric from the sustainability metrics in VMware vRealize Operations might display in wrong units**

  In the sustainability metrics in VMware vRealize Operations, you might see the value of **Power|Total Energy (Wh)** per virtual machine higher than the ESXi host on which the VM is hosted. The issue occurs because after measuring the total energy consumed by the VM, the **power.energy** performance counter is calculated and reported in millijoules instead of joules.

  This issue is resolved in this release.
- **PR 2902475: Windows virtual machines of hardware version 19 that have Virtualization-Based Security (VBS) enabled might fail with a blue diagnostic screen on ESXi hosts running on AMD processors**

  In ESXi hosts running on AMD processors, Windows virtual machines of hardware version 19 with VBS enabled might fail with a blue diagnostic screen due to a processor mode misconfiguration error. In the **vmware.log** file, you see errors such as **vcpu-0 - WinBSOD: Synthetic MSR[0xx0000x00] 0xxxx**.

  This issue is resolved in this release.
- **PR 3087946: vSphere Lifecycle Manager compliance scan might show a warning for a CPU that is supported**

  Due to an internal error, even if a CPU model is listed as supported in the VMware Compatibility Guide, in the vSphere Client you might see a warning such as **The CPU on the host is not supported by the image** during a compliance scan by using a vSphere Lifecycle Manager image. The warning does not prevent you from completing an update or upgrade.

  This issue is resolved in this release.
- **PR 3116848: Virtual machines with Virtualization-Based Security (VBS) enabled might fail with a blue diagnostic screen after a migration**

  When you migrate virtual machines with VBS enabled that reside on ESXi hosts running on AMD processors, such VMs might fail with a blue diagnostic screen on the target host due to a guest interruptibility state error.

  This issue is resolved in this release.
- **PR 3010502: If you override a networking policy for a port group and then revert the change, the override persists after an ESXi host reboot**

  When you override a networking policy such as Teaming, Security, or Shaping for a port group, and then revert the change, after a reboot of the ESXi host, you might still see the override setting. For example, if you accept promiscuous mode activation on a port group level, then revert the mode back to Reject, and reboot the ESXi host, the setting is still Accept.

  This issue is resolved in this release.

- **PR 3118090: The autocomplete attribute in forms for web access is not disabled on password and username fields**
  Your remote web server might contain an HTML form field that has an input of type **password** and **username** where the **autocomplete** attribute is not set to **off**. As a result, you might see a warning by security scanners such as **AutoComplete Attribute Not Disabled for Password in Form Based Authentication**. The setting of the **autocomplete** attribute to **on** does not directly put a risk on web servers, but in certain browsers, user credentials in such forms might be saved and potentially lead to a loss of confidentiality.
  This issue is resolved in this release. The fix makes sure the attribute **autocomplete** is set to **off** in password and username fields to prevent browsers from caching credentials.
- **PR 3078875: Cannot set IOPS limit for vSAN file service objects**
  vSAN Distributed File System (vDFS) objects do not support IOPS limit. You cannot set the IOPS limit for vSAN file service objects.
  This issue is resolved in this release. With the fix, you can set an IOPSLimit policy with vSAN file service objects.
- **PR 3069298: In vSphere Client, you do not see the asset tag for some servers**
  In vSphere Client, when you navigate to **Configure** > **Hardware** > **Overview**, for some servers you do not see any asset tag listed.
  This issue is resolved in this release. The fix ensures that vCenter receives either baseboard info (Type2) asset tag or chassis info(Type3) asset tag for the server. You see the chassis info asset tag when the baseboard info asset tag for the server is empty.
- **PR 3074121: Network configuration lost after vSAN upgrade to 7.0 or later**
  When you upgrade a vSAN host from a pre-6.2 release to 7.0 or later, the VMkernel port tagging for vSAN might be lost. If this occurs, vSAN networking configuration is missing after the upgrade.
  This issue is resolved in this release. The fix prevents the issue to occur on ESXi 7.0 Update 3l and later. If you already face the issue, upgrading to ESXi 7.0 Update 3l does not automatically resolve the issue, but you can manually fix it by enabling VMkernel traffic for vSAN on the ESXi host.
- **PR 3085003: Cannot enable vSAN File Service with uploaded OVF files**
  You cannot enable vSAN File Service if the vCenter does not have Internet access.
  This issue is resolved in this release.
- **PR 3088608: Virtual machines might fail with a core dump while resuming from a checkpoint or after migration**
  In rare cases, when a data breakpoint is enabled in the guest OS of virtual machines, during checkpoint resume or after a vSphere vMotion migration, an internal virtualization data structure might be accessed before it is allocated. As a result, the virtual machines crash with core dump and an error such as:
  vcpu-1:VMM fault 14: src=MONITOR rip=0xfffffffffc0XXe00 regs=0xfffffffffcXXXdc0 LBR stack=0xfffffffffcXXXaXX.
  This issue is resolved in this release.

The sfcb daemon might fail with a core dump while installing a third-party CIM provider

The sfcb daemon might try to access already freed memory when registering a CIM provider and fail with a core dump while installing a third-party CIM provider, such as Dell OpenManage Server Administrator for example.

This issue is resolved in this release.

esx-update_7.0.3-0.85.21424296

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A

Affected Software	N/A
Affected VIBs	• VMware_bootbank_esx-update_7.0.3-0.85.21424296 • VMware_bootbank_loadesx_7.0.3-0.85.21424296
PRs Fixed	N/A
CVE numbers	N/A

Updates the `loadesx` and `esx-update` VIBs.

Broadcom-ntg3_4.1.9.0-4vmw.703.0.85.21424296

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMW_bootbank_ntg3_4.1.9.0-4vmw.703.0.85.21424296
PRs Fixed	3083426
CVE numbers	N/A

Update the `ntg3` VIB to resolve the following issue:

PR 3083426: You might see jumbo frames packet loss when NICs using the ntg3 driver are connected to certain Dell switches

When NICs using the `ntg3` driver such as Broadcom BCM5719 and BCM5720 are connected to certain models of Dell switches, including but not limited to S4128T-ON and S3048-ON, such NICs might incorrectly drop some of the received packets greater than 6700 bytes. This might cause very low network performance or loss of connectivity.

This issue is resolved in this release. The `ntg3` driver version 4.1.9.0, which is released with ESXi 7.0 Update 3l, contains the fix.

VMware-vmkusb_0.1-8vmw.703.0.85.21424296

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A

Affected VIBs	• VMW_bootbank_vmkusb_0.1-8vmw.703.0.85.21424296
PRs Fixed	N/A
CVE numbers	N/A

Updates the `vmkusb` VIB.

VMware-NVMe-PCIe_1.2.3.16-2vmw.703.0.85.21424296

Patch Category	Bugfix
Patch Severity	Critical
Host Reboot Required	Yes
Virtual Machine Migration or Shutdown Required	Yes
Affected Hardware	N/A
Affected Software	N/A
Affected VIBs	• VMW_bootbank_nvme-pcie_1.2.3.16-2vmw.703.0.85.21424296
PRs Fixed	3086841, 3104368, 3061328
CVE numbers	N/A

Update the `nvme-pcie` VIB to resolve the following issues:

PR 3086841: Third-party multipathing plug-ins report "Invalid length RTPG Discriptor" warning while running on the SCSI to NVMe translation stack

In case of an extended header format in the NVMe to SCSI translation layer, third-party multipathing plug-ins such as PowerPath might not account for the extended header size of 4 bytes. As a result, in the `vmkernel.log` , you see an `Invalid length RTPG Descriptor` warning.

This issue is resolved in this release. The fix accounts for 4 bytes of extended headers.

PR 3104368: You cannot install ESXi or create datastores on an NVMe device

When installing ESXi or creating a VMFS datastore on an NVMe device, the native NVMe driver might need to handle a Compare and Write fused operation. According to NVMe specs, the Compare and Write commands must be inserted next to each other in the same Submission Queue, and the Submission Queue Tail doorbell pointer update must indicate both commands as part of one doorbell update. The native NVMe driver puts the two commands together in one Submission Queue, but writes the doorbell for each command separately. As a result, the device firmware might complete the fused commands with an error and fail to create a VMFS datastore. Since creating a VMFS datastore on a device is a prerequisite for successful ESXi installation, you might not be able to install ESXi on such NVMe devices.

This issue is resolved in this release.

PR 3061328: Cannot clear vSAN health check: NVMe device can be identified

If the vSAN health check indicates that an NVMe device cannot be identified, the warning might not be cleared after you correctly select the device model.

This issue is resolved in this release.

ESXi_7.0.3-0.80.21422485

PRs Fixed	N/A
CVE numbers	CVE-2023-1017, CVE-2023-1018

The ESXi and esx-update bulletins are dependent on each other. Always include both in a single ESXi host patch baseline or include the rollup bulletin in the baseline to avoid failure during host patching.

Updates the `esx-dvfilter-generic-fastpath`, `vsan`, `bmcal`, `crx`, `esx-ui`, `esxio-combiner`, `vsanhealth`, `native-misc-drivers`, `gc`, `cpu-microcode`, `vdfs`, `esx-xserver`, `esx-base`, and `trx` VIBs to resolve the following issues:

ESXi 7.0 Update 3l provides the following security updates:

- The Python package is updated to versions 3.8.16/3.5.10.
- The ESXi userworld libxml2 library is updated to version 2.10.3.
- The cURL library is updated to version 7.86.0.
- The Expat XML parser is updated to version 2.5.0.
- The SQLite database is updated to version 3.40.1.
- The zlib library is updated to 1.2.13.

CVE numbers	N/A

Updates the `loadesx` and `esx-update` VIBs.

- The following VMware Tools ISO images are bundled with ESXi 7.0 Update 3l:
  - **windows.iso**: VMware Tools 12.1.5 supports Windows 7 SP1 or Windows Server 2008 R2 SP1 and later.
  - **linux.iso**: VMware Tools 10.3.25 ISO image for Linux OS with **glibc** 2.11 or later.

  The following VMware Tools ISO images are available for download:
  - VMware Tools 11.0.6:
    - **windows.iso**: for Windows Vista (SP2) and Windows Server 2008 Service Pack 2 (SP2).
  - VMware Tools 10.0.12:
    - **winPreVista.iso**: for Windows 2000, Windows XP, and Windows 2003.
    - **linuxPreGLibc25.iso**: supports Linux guest operating systems earlier than Red Hat Enterprise Linux (RHEL) 5, SUSE Linux Enterprise Server (SLES) 11, Ubuntu 7.04, and other distributions with **glibc** version earlier than 2.5.
  - **solaris.iso**: VMware Tools image 10.3.10 for Solaris.
  - **darwin.iso**: Supports Mac OS X versions 10.11 and later. VMware Tools 12.1.0 was the last regular release for macOS. Refer VMware knowledge base article 88698 for details.

  Follow the procedures listed in the following documents to download VMware Tools for platforms not bundled with ESXi:
  - Updating VMware Tools
  - VMware Tools for hosts provisioned with Auto Deploy
  - What Every vSphere Admin Must Know About VMware Tools
  - Earlier versions of VMware Tools
  - VMware Tools 12.1.5 Release Notes

ESXi-7.0U3l-21424296-standard

Profile Name	ESXi-7.0U3l-21424296-standard

Related CVE numbers	CVE-2023-1017, CVE-2023-1018

This patch updates the following issues:

- In the vSphere Client and the ESXi Host Client, you might see incorrect number of sockets and respectively cores per socket when you change the NPS setting on an AMD EPYC 9004 server from the default of 1, or Auto, to another value, such as 2 or 4.
- Due to a rare race condition during a Fast Suspend Resume (FSR) operation on a VM with shared pages between VMs, ESXi hosts might fail with a purple diagnostic screen with an error such as `PFrame_IsBackedByLPage` in the backtrace. The issue occurs during vSphere Storage vMotion operations or hot-adding a device.
- Packet capture with the `-c` option of the `pktcap-uw` utlity in heavy network traffic might be slower than packet capture without the option. You might also see a delay in capturing packets, so that the last package counted has a timestap few seconds earlier than the stop time of the function. The issue results from the `File_GetSize` function to check file sizes, which is slow in VMFS environments and causes low performance of `pktcap-uw` .

- In the `syslog` file you might see frequent log messages such as:
  `2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info] *** Received pre-CEE DCBX Packet on port: vmnicX`
  `2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info]2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info] Src MAC: xc:xc:X0:0X:xc:xx`
  `2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info] Dest MAC: X0:xb:xb:fx:0X:X1`
  `2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info] 2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info] Port ID TLV:`
  `2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info] ifName:`
  The issue occurs because the Data Center Bridging (DCB) daemon, `dcbd` , on the ESXi host records unnecessary messages at `/var/log/syslog.log` . As a result, the log file might quickly fill up with `dcbd` logs.
- In some cases, a timed-wait system call in the VMkernel might return too early. As a result, some applications, such as the System Health Agent, might take up to 100% of the CPU usage on one of the ESXi host cores.
- Due to an issue with the IPv6 loopback interfaces, you might not see virtual machine image details in the **Summary** tab of the vSphere Client.
- If the number of paths from an ESXi host using NMP SATP ALUA to storage exceed 255, ESXi ignores part of the ALUA information reported by the target and incorrectly retains some of the path state as active optimised. As a result, some I/Os use the non-optimised path to the storage device and cause latency issues..
- In some cases, during an ESXi host shutdown, helper queues of device probe requests get deleted, but the reference to the device remains. As a result, the ESXi host reboot stops with a message such as `initializing init_VMKernelShutdownHelper: (14/39) ShutdownSCSICleanupForDevTearDown` in the Direct Console User Interface (DCUI).
- Due to a race condition during an Instant Clone operation, VM memory pages might be corrupted and the ESXi host might fail with a purple diagnostic screen. You see errors such as `VmMemMigrate_MarkPagesCow` or `AsyncRemapProcessVMRemapList` in the backtrace.
- In some environments with SATP plug-ins such as `satp_alua` and `satp_alua_cx` , bringing all paths to a LUN online might require several scans. As a result, a storage failover operation might take long. For example, with 4 paths to a LUN, it might take up to 20 minutes to bring the 4 paths online.
- After vSphere vMotion operations across vCenter Server instances for VMs that have vSphere tags, it is possible that the tags do not exist in the target location. The issue only occurs in migration operations between vCenter Server instances that do not share storage.
- When you set the multicast filter mode of an NSX Virtual Switch for NVDS, the mode might intermittently revert from legacy to snooping.
- When you run a Nessus scan, which internally runs a SYN scan, to detect active ports on an ESXi host, the iofiltervpd service might shut down. The service cannot be restarted within the max retry attempts due to the SYN scan.
- If a VIB containing a new kernel module is installed before you run any of the restore config procedures described in VMware knowledge base article 2042141, you see no change in the config after the ESXi host reboots. For example, if you attempt to restore the ESXi config immediately after installing the NSX VIB, the ESXi host reboots, but no changes in the config are visible. The issue occurs due to a logical fault in the updates of the bootbank partition used for ESXi host reboots after a new kernel module VIB is installed.
- Listing files of mounted NFS 4.1 Azure storage might not work as expected, because although the files exist and you can open them by name, the `ls` command on an ESXi host by using SSH does not show any files.
- Starting with ESXi 7.0 Update 1, the `vpxa.cfg` file no longer exists and the vpxa configuration belongs to the ESXi Configuration Store (`ConfigStore`). When you upgrade an ESXi host from a version earlier than 7.0 Update 1 to a later version, the fields `Vpx.Vpxa.config.nfc.loglevel` and `Vpx.Vpxa.config.httpNfc.accessMode` in the `vpxa.cfg` file might cause the ESXi host to fail with a purple diagnostic screen during the conversion from `vpxa.cfg` format to `ConfigStore` format. The issue occurs due to discrepancies in the NFC log level between `vpxa.cfg` and `ConfigStore` , and case-sensitive values.
- In rare cases, multiple concurrent open and close operations on datastores, for example when vSphere DRS triggers multiple migration tasks, might cause some VMs to take longer to complete in-flight disk I/Os. As a result, such virtual

machines might take longer to respond or become unresponsive for a short time. The issue is more likely to occur on VMs that have multiple virtual disks over different datastores.

- During an API call to reload a virtual machine from one ESXi host to another, the `externalId` in the VM port data file might be lost. As a result, after the VM reloads, the VM virtual NIC might not be able to connect to a LSP.
- After upgrading to ESXi 7.0 Update 3i, you might not be able to attach an existing virtual machine disk (VMDK) to a VM by using the VMware Host Client, which is used to connect to and manage single ESXi hosts. The issue does not affect the vSphere Client.
- Due to a race condition between the Create and Delete resource pool workflows, a freed pointer in the VMFS resource pool cache might get dereferenced. As a result, ESXi hosts might fail with a purple diagnostic screen and error such as:
  `@BlueScreen: #PF Exception 14 in world 2105491:res3HelperQu IP 0x420032a21f55 addr 0x0`
- With the batch `QueryUnresolvedVmfsVolume` API, you can query and list unresolved VMFS volumes or LUN snapshots. You can then use other batch APIs to perform operations, such as re-signaturing specific unresolved VMFS volumes. By default, when the API `QueryUnresolvedVmfsVolume` is invoked on a host, the system performs an additional filesystem liveness check for all unresolved volumes that are found. The liveness check detects whether the specified LUN is mounted on other hosts, whether an active VMFS heartbeat is in progress, or if there is any filesystem activity. This operation is time consuming and requires at least 16 seconds per LUN. As a result, when your environment has a large number of snapshot LUNs, the query and listing operation might take significant time.
- This problem can occur when vCenter manages multiple clusters, and the vCenter VM runs on one of the clusters. If you shut down the cluster where the vCenter VM resides, the following error can occur during the shutdown operation: `'NoneType' object has no attribute '_moId'`. The vCenter VM is not powered off.
- This problem can occur when vCenter manages multiple clusters and runs several shut down and restart cluster operations in parallel. For example, if you shut down 3 clusters and restart the vSAN health service or the vCenter VM, and you restart one of the 3 clusters before the others, the **Restart Cluster** option might be available for the first vSAN cluster, but not for the other clusters.
- Unexpected time drift can occur intermittently on a vSAN cluster when a single vCenter Server manages several vSAN clusters, due to internal delays in VPXA requests. In the vSphere Client, in the vSAN Health tab, you see the status of **Time is synchronized across hosts and VC** changing from green to yellow and back to green.
- When you enable the `ToolsRamdisk` advanced option that makes sure the `/vmtools` partition is always on a RAM disk rather than on a USB or SD-card, installing or updating the `tools-light` VIB does not update the content of the RAM disk automatically. Instead, you must reboot the host so that the RAM disk updates and the new VM Tools version is available for the VMs.
- A rare race condition caused by memory reclamation for some performance optimization processes in vSphere vMotion might cause ESXi hosts to fail with a purple diagnostic screen.
- If your environment has both small and large file block clusters mapped to one affinity rule, when you add a cluster, the Affinity Manager might allocate more blocks for files than the actual volume of the datastore. As a result, ESXi hosts randomly fail with a purple diagnostic screen with error `Exception 14 in world #######.`
- This issue occurs when you view health details of any health check in the history view. In the vSphere Client, in the Skyline Health tab, you see a message such as `No data available for the selected time period.` The issue occurs when a query to the historical health records fails due to timestamps with an incorrect time zone.
- The logger command of some logger clients might not pass the right facility code to the ESXi syslog daemon and cause incorrect facility or severity values in ESXi syslog log messages.
- In rare cases, in a heavy workload, two LVM tasks that perform updating and querying on the device schedule in an ESXi host might run in parallel and cause a synchronization issue. As a result, the ESXi host might fail with a purple diagnostic screen and a messages similar to `LVMIoctlInt@com.vmware.lvm.ut#nover+0x1018 stack: 0xXXXXX and Addr3ResolvePhysVector@esx#nover+0x68 stack: 0xXXXX` in the backtrace.
- In some cases, while an ESXi host boots, some dynamically discovered iSCSI targets might get deleted. As a result, after the boot completes, you might no longer see some iSCSI LUNs. The issue is more likely to occur in environments with Challenge-Handshake Authentication Protocol
  (CHAP) enabled for iSCSI.

- In busy environments with many rescans by using a software iSCSI adapter, the VMware Host Client might intermittently stop displaying the adapter. The issue occurs only with target arrays which return target portals with both IPv4 and IPv6 addresses during discovery by using the `SendTargets` method.
- A rare issue with calculating the Max Queue Depth per datastore device might cause queue depth mismatch warnings from the underlying SCSI layer. As a result, when you disable Storage I/O Control on datastores, you might see high read I/O on all ESXi hosts.
- Due to missing configuration for `stats-log` in the file `/etc/vmware/vvold/config.xml`, you might see multiple `-1.log` files to fill up the `/ramdisk` partition after an upgrade to ESXi 7.0 Update 3 and later.
- If a username or password in a network proxy contains any escape character, the environment fails to send network requests through the proxy.
- If you configure an NTP server on an ESXi host with additional parameters along with `hostname`, such as `min_poll` or `max_poll`, the command `esxcli system ntp test` might fail to resolve the IP address of that server. This issue occurs because in such configurations, the NTP name resolution applies to the entire server config instead of just the host name.
- After upgrading to ESXi 7.0 Update 2 and later, a virtual machine might not discover some USB devices attached to it, such as an Eaton USB UPS, and fail to communicate with the device properly.
- If you clone a VM, including the guest customization specs, move the VMDK file to another datastore and make it thick provisioned, and then power on the VM, the guest OS customization might not be preserved. In the hostd logs, you see an Event Type Description such as `The customization component failed to set the required parameters inside the guest operating system.`
  The issue occurs because while moving the VMDK file of the cloned VM to another datastore, the new `pathName` for the guest OS customization might temporarily be the same as the `oldPathName` and the package gets deleted.
- Improper sizing of the resource needs for the hostd service on an ESXi host might cause some virtual machine-related tasks to fail when you use vSphere APIs for I/O Filtering (VAIO) for VMware or third-party backup applications. For example, when a VAIO filter is attached to one or more virtual disks of a virtual machine, such VMs might fail to perform backups or power-on after a backup.
- A rare file corruption issue might occur when multiple ESXi hosts do a simultaneous file append operation on an NFSv3 datastore. As a result, if you use the Govc open source command-line utility to perform administrative actions on a vCenter instance, you might see reports with inconsistent values. For example, if you run the command `govc disk.ls` to list all FCDs in a newly created datastore, you see a different number of disks from what you expect.
- In rare cases, when a VMFS volume is closed immediately after it is opened, one of the threads in the opening process might race with a thread in the closing process and take a rare error handling path that can exit without unlocking a locked spinlock. As a result, the ESXi host might fail with a purple diagnostic screen with a message in the backtrace such as: `@BlueScreen: VERIFY bora/vmkernel/sched/cpusched.c:11154.`
- Due to reservation conflicts, WSFC applications might lose connectivity to a virtual volume-based disk after a rebind operation on that disk.
- In rare situations, the management agent that vSphere HA deploys on ESXi hosts, Fault Domain Manager (FDM), might fail to acquire a vSAN datastore in the first attempt before an exceptional condition, such as power outage, occurs. As a result, vSphere HA failover for virtual machines on that datastore might not be successful. In the vSphere Client, you see a message such as `This virtual machine failed to become vSphere HA Protected and HA may not attempt to restart it after a failure.` Successive attempts of FDM to acquire the vSAN datastore might also fail.
- In the sustainability metrics in VMware vRealize Operations, you might see the value of **Power|Total Energy (Wh)** per virtual machine higher than the ESXi host on which the VM is hosted. The issue occurs because after measuring the total energy consumed by the VM, the **power.energy** performance counter is calculated and reported in millijoules instead of joules.
- In ESXi hosts running on AMD processors, Windows virtual machines of hardware version 19 with VBS enabled might fail with a blue diagnostic screen due to a processor mode misconfiguration error. In the `vmware.log` file, you see errors such as `vcpu-0 - WinBSOD: Synthetic MSR[0xx0000x00] 0xxxx.`
- Due to an internal error, even if a CPU model is listed as supported in the VMware Compatibility Guide, in the vSphere Client you might see a warning such as `The CPU on the host is not supported by the image` during a

compliance scan by using a vSphere Lifecycle Manager image. The warning does not prevent you from completing an update or upgrade.
- When you migrate virtual machines with VBS enabled that reside on ESXi hosts running on AMD processors, such VMs might fail with a blue diagnostic screen on the target host due to a guest interruptibility state error.
- When you override a networking policy such as Teaming, Security, or Shaping for a port group, and then revert the change, after a reboot of the ESXi host, you might still see the override setting. For example, if you accept promiscuous mode activation on a port group level, then revert the mode back to Reject, and reboot the ESXi host, the setting is still Accept.
- Your remote web server might contain an HTML form field that has an input of type `password` and `username` where the `autocomplete` attribute is not set to `off` . As a result, you might see a warning by security scanners such as `AutoComplete Attribute Not Disabled for Password in Form Based Authentication` . The setting of the `autocomplete` attribute to `on` does not directly put a risk on web servers, but in certain browsers, user credentials in such forms might be saved and potentially lead to a loss of confidentiality.
- vSAN Distributed File System (vDFS) objects do not support IOPS limit. You cannot set the IOPS limit for vSAN file service objects.
- In vSphere Client, when you navigate to **Configure** > **Hardware** > **Overview**, for some servers you do not see any asset tag listed.
- When you upgrade a vSAN host from a pre-6.2 release to 7.0 or later, the VMkernel port tagging for vSAN might be lost. If this occurs, vSAN networking configuration is missing after the upgrade.
- You cannot enable vSAN File Service if the vCenter does not have Internet access.
- In rare cases, when a data breakpoint is enabled in the guest OS of virtual machines, during checkpoint resume or after a vSphere vMotion migration, an internal virtualization data structure might be accessed before it is allocated. As a result, the virtual machines crash with core dump and an error such as: vcpu-1:VMM fault 14: src=MONITOR rip=0xffffffffc0XXe00 regs=0xffffffffcXXXdc0 LBR stack=0xffffffffcXXXaXX.
- When NICs using the `ntg3` driver such as Broadcom BCM5719 and BCM5720 are connected to certain models of Dell switches, including but not limited to S4128T-ON and S3048-ON, such NICs might incorrectly drop some of the received packets greater than 6700 bytes. This might cause very low network performance or loss of connectivity.
- In case of an extended header format in the NVMe to SCSI translation layer, third-party multipathing plug-ins such as PowerPath might not account for the extended header size of 4 bytes. As a result, in the `vmkernel.log` , you see an `Invalid length RTPG Descriptor` warning.
- When installing ESXi or creating a VMFS datastore on an NVMe device, the native NVMe driver might need to handle a Compare and Write fused operation. According to NVMe specs, the Compare and Write commands must be inserted next to each other in the same Submission Queue, and the Submission Queue Tail doorbell pointer update must indicate both commands as part of one doorbell update. The native NVMe driver puts the two commands together in one Submission Queue, but writes the doorbell for each command separately. As a result, the device firmware might complete the fused commands with an error and fail to create a VMFS datastore. Since creating a VMFS datastore on a device is a prerequisite for successful ESXi installation, you might not be able to install ESXi on such NVMe devices.
- If the vSAN health check indicates that an NVMe device cannot be identified, the warning might not be cleared after you correctly select the device model.

ESXi-7.0U3l-21424296-no-tools

Profile Name	ESXi-7.0U3l-21424296-no-tools
Build	For build information, see Patches Contained in this Release.
Vendor	VMware, Inc.
Release Date	March 30, 2023
Acceptance Level	PartnerSupported
Affected Hardware	N/A
Affected Software	N/A

Affected VIBs	• VMware_bootbank_esx-dvfilter-generic-fastpath_7.0.3-0.85.21424296 • VMware_bootbank_vsan_7.0.3-0.85.21424296 • VMware_bootbank_bmcal_7.0.3-0.85.21424296 • VMware_bootbank_crx_7.0.3-0.85.21424296 • VMware_bootbank_esx-ui_2.9.2-21141530 • VMware_bootbank_esxio-combiner_7.0.3-0.85.21424296 • VMware_bootbank_vsanhealth_7.0.3-0.85.21424296 • VMware_bootbank_native-misc-drivers_7.0.3-0.85.21424296 • VMware_bootbank_gc_7.0.3-0.85.21424296 • VMware_bootbank_cpu-microcode_7.0.3-0.85.21424296 • VMware_bootbank_vdfs_7.0.3-0.85.21424296 • VMware_bootbank_esx-xserver_7.0.3-0.85.21424296 • VMware_bootbank_esx-base_7.0.3-0.85.21424296 • VMware_bootbank_trx_7.0.3-0.85.21424296 • VMware_bootbank_esx-update_7.0.3-0.85.21424296 • VMware_bootbank_loadesx_7.0.3-0.85.21424296 • VMW_bootbank_ntg3_4.1.9.0-4vmw.703.0.85.21424296 • VMW_bootbank_vmkusb_0.1-8vmw.703.0.85.21424296 • VMW_bootbank_nvme-pcie_1.2.3.16-2vmw.703.0.85.21424296
PRs Fixed	3057026, 3062185, 3040049, 3061156, 3023389, 3062861, 3089449, 3081870, 3082900, 3033157, 3090683, 3075786, 3074392, 3081275, 3080022, 3083314, 3084812, 3074360, 3092270, 3076977, 3051685, 3082477, 3082282, 3082427, 3077163, 3087219, 3074187, 3082431, 3050562, 3072430, 3077072, 3077060, 3046875, 3082991, 3083473, 3051059, 3091256, 3074912, 3058993, 3063987, 3072500, 3060661, 3076188, 3049652, 2902475, 3087946, 3116848, 3010502, 3118090, 3078875, 3069298, 3074121, 3083426, 3086841, 3104368, 3061328
Related CVE numbers	CVE-2023-1017, CVE-2023-1018

This patch updates the following issues:

- In the vSphere Client and the ESXi Host Client, you might see incorrect number of sockets and respectively cores per socket when you change the NPS setting on an AMD EPYC 9004 server from the default of 1, or Auto, to another value, such as 2 or 4.
- Due to a rare race condition during a Fast Suspend Resume (FSR) operation on a VM with shared pages between VMs, ESXi hosts might fail with a purple diagnostic screen with an error such as `PFrame_IsBackedByLPage` in the backtrace. The issue occurs during vSphere Storage vMotion operations or hot-adding a device.
- Packet capture with the `-c` option of the `pktcap-uw` utlity in heavy network traffic might be slower than packet capture without the option. You might also see a delay in capturing packets, so that the last package counted has a timestap few seconds earlier than the stop time of the function. The issue results from the `File_GetSize` function to check file sizes, which is slow in VMFS environments and causes low performance of `pktcap-uw` .

- In the `syslog` file you might see frequent log messages such as:
  `2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info] *** Received pre-CEE DCBX Packet on port: vmnicX`
  `2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info]2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info] Src MAC: xc:xc:X0:0X:xc:xx`
  `2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info] Dest MAC: X0:xb:xb:fx:0X:X1`
  `2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info] 2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info] Port ID TLV:`
  `2022-03-27T00:xx:xx.xxxx dcbd[xxxx]: [info] ifName:`
  The issue occurs because the Data Center Bridging (DCB) daemon, `dcbd` , on the ESXi host records unnecessary messages at `/var/log/syslog.log` . As a result, the log file might quickly fill up with `dcbd` logs.
- In some cases, a timed-wait system call in the VMkernel might return too early. As a result, some applications, such as the System Health Agent, might take up to 100% of the CPU usage on one of the ESXi host cores.
- Due to an issue with the IPv6 loopback interfaces, you might not see virtual machine image details in the **Summary** tab of the vSphere Client.
- If the number of paths from an ESXi host using NMP SATP ALUA to storage exceed 255, ESXi ignores part of the ALUA information reported by the target and incorrectly retains some of the path state as active optimised. As a result, some I/Os use the non-optimised path to the storage device and cause latency issues..
- In some cases, during an ESXi host shutdown, helper queues of device probe requests get deleted, but the reference to the device remains. As a result, the ESXi host reboot stops with a message such as `initializing init_VMKernelShutdownHelper: (14/39) ShutdownSCSICleanupForDevTearDown` in the Direct Console User Interface (DCUI).
- Due to a race condition during an Instant Clone operation, VM memory pages might be corrupted and the ESXi host might fail with a purple diagnostic screen. You see errors such as `VmMemMigrate_MarkPagesCow` or `AsyncRemapProcessVMRemapList` in the backtrace.
- In some environments with SATP plug-ins such as `satp_alua` and `satp_alua_cx` , bringing all paths to a LUN online might require several scans. As a result, a storage failover operation might take long. For example, with 4 paths to a LUN, it might take up to 20 minutes to bring the 4 paths online.
- After vSphere vMotion operations across vCenter Server instances for VMs that have vSphere tags, it is possible that the tags do not exist in the target location. The issue only occurs in migration operations between vCenter Server instances that do not share storage.
- When you set the multicast filter mode of an NSX Virtual Switch for NVDS, the mode might intermittently revert from legacy to snooping.
- When you run a Nessus scan, which internally runs a SYN scan, to detect active ports on an ESXi host, the iofiltervpd service might shut down. The service cannot be restarted within the max retry attempts due to the SYN scan.
- If a VIB containing a new kernel module is installed before you run any of the restore config procedures described in VMware knowledge base article 2042141, you see no change in the config after the ESXi host reboots. For example, if you attempt to restore the ESXi config immediately after installing the NSX VIB, the ESXi host reboots, but no changes in the config are visible. The issue occurs due to a logical fault in the updates of the bootbank partition used for ESXi host reboots after a new kernel module VIB is installed.
- Listing files of mounted NFS 4.1 Azure storage might not work as expected, because although the files exist and you can open them by name, the `ls` command on an ESXi host by using SSH does not show any files.
- Starting with ESXi 7.0 Update 1, the `vpxa.cfg` file no longer exists and the vpxa configuration belongs to the ESXi Configuration Store (`ConfigStore`). When you upgrade an ESXi host from a version earlier than 7.0 Update 1 to a later version, the fields `Vpx.Vpxa.config.nfc.loglevel` and `Vpx.Vpxa.config.httpNfc.accessMode` in the `vpxa.cfg` file might cause the ESXi host to fail with a purple diagnostic screen during the conversion from `vpxa.cfg` format to `ConfigStore` format. The issue occurs due to discrepancies in the NFC log level between `vpxa.cfg` and `ConfigStore` , and case-sensitive values.
- In rare cases, multiple concurrent open and close operations on datastores, for example when vSphere DRS triggers multiple migration tasks, might cause some VMs to take longer to complete in-flight disk I/Os. As a result, such virtual

machines might take longer to respond or become unresponsive for a short time. The issue is more likely to occur on VMs that have multiple virtual disks over different datastores.

- During an API call to reload a virtual machine from one ESXi host to another, the `externalId` in the VM port data file might be lost. As a result, after the VM reloads, the VM virtual NIC might not be able to connect to a LSP.
- After upgrading to ESXi 7.0 Update 3i, you might not be able to attach an existing virtual machine disk (VMDK) to a VM by using the VMware Host Client, which is used to connect to and manage single ESXi hosts. The issue does not affect the vSphere Client.
- Due to a race condition between the Create and Delete resource pool workflows, a freed pointer in the VMFS resource pool cache might get dereferenced. As a result, ESXi hosts might fail with a purple diagnostic screen and error such as:
  `@BlueScreen: #PF Exception 14 in world 2105491:res3HelperQu IP 0x420032a21f55 addr 0x0`
- With the batch `QueryUnresolvedVmfsVolume` API, you can query and list unresolved VMFS volumes or LUN snapshots. You can then use other batch APIs to perform operations, such as re-signaturing specific unresolved VMFS volumes. By default, when the API `QueryUnresolvedVmfsVolume` is invoked on a host, the system performs an additional filesystem liveness check for all unresolved volumes that are found. The liveness check detects whether the specified LUN is mounted on other hosts, whether an active VMFS heartbeat is in progress, or if there is any filesystem activity. This operation is time consuming and requires at least 16 seconds per LUN. As a result, when your environment has a large number of snapshot LUNs, the query and listing operation might take significant time.
- This problem can occur when vCenter manages multiple clusters, and the vCenter VM runs on one of the clusters. If you shut down the cluster where the vCenter VM resides, the following error can occur during the shutdown operation: `'NoneType' object has no attribute '_moId'`. The vCenter VM is not powered off.
- This problem can occur when vCenter manages multiple clusters and runs several shut down and restart cluster operations in parallel. For example, if you shut down 3 clusters and restart the vSAN health service or the vCenter VM, and you restart one of the 3 clusters before the others, the **Restart Cluster** option might be available for the first vSAN cluster, but not for the other clusters.
- Unexpected time drift can occur intermittently on a vSAN cluster when a single vCenter Server manages several vSAN clusters, due to internal delays in VPXA requests. In the vSphere Client, in the vSAN Health tab, you see the status of **Time is synchronized across hosts and VC** changing from green to yellow and back to green.
- When you enable the `ToolsRamdisk` advanced option that makes sure the `/vmtools` partition is always on a RAM disk rather than on a USB or SD-card, installing or updating the `tools-light` VIB does not update the content of the RAM disk automatically. Instead, you must reboot the host so that the RAM disk updates and the new VM Tools version is available for the VMs.
- A rare race condition caused by memory reclamation for some performance optimization processes in vSphere vMotion might cause ESXi hosts to fail with a purple diagnostic screen.
- If your environment has both small and large file block clusters mapped to one affinity rule, when you add a cluster, the Affinity Manager might allocate more blocks for files than the actual volume of the datastore. As a result, ESXi hosts randomly fail with a purple diagnostic screen with error `Exception 14 in world #######.`
- This issue occurs when you view health details of any health check in the history view. In the vSphere Client, in the Skyline Health tab, you see a message such as `No data available for the selected time period.` The issue occurs when a query to the historical health records fails due to timestamps with an incorrect time zone.
- The logger command of some logger clients might not pass the right facility code to the ESXi syslog daemon and cause incorrect facility or severity values in ESXi syslog log messages.
- In rare cases, in a heavy workload, two LVM tasks that perform updating and querying on the device schedule in an ESXi host might run in parallel and cause a synchronization issue. As a result, the ESXi host might fail with a purple diagnostic screen and a messages similar to `LVMIoctlInt@com.vmware.lvm.ut#nover+0x1018 stack: 0xXXXXX and Addr3ResolvePhysVector@esx#nover+0x68 stack: 0xXXXX` in the backtrace.
- In some cases, while an ESXi host boots, some dynamically discovered iSCSI targets might get deleted. As a result, after the boot completes, you might no longer see some iSCSI LUNs. The issue is more likely to occur in environments with Challenge-Handshake Authentication Protocol
  (CHAP) enabled for iSCSI.

- In busy environments with many rescans by using a software iSCSI adapter, the VMware Host Client might intermittently stop displaying the adapter. The issue occurs only with target arrays which return target portals with both IPv4 and IPv6 addresses during discovery by using the `SendTargets` method.
- A rare issue with calculating the Max Queue Depth per datastore device might cause queue depth mismatch warnings from the underlying SCSI layer. As a result, when you disable Storage I/O Control on datastores, you might see high read I/O on all ESXi hosts.
- Due to missing configuration for `stats-log` in the file `/etc/vmware/vvold/config.xml`, you might see multiple `-1.log` files to fill up the `/ramdisk` partition after an upgrade to ESXi 7.0 Update 3 and later.
- If a username or password in a network proxy contains any escape character, the environment fails to send network requests through the proxy.
- If you configure an NTP server on an ESXi host with additional parameters along with `hostname`, such as `min_poll` or `max_poll`, the command `esxcli system ntp test` might fail to resolve the IP address of that server. This issue occurs because in such configurations, the NTP name resolution applies to the entire server config instead of just the host name.
- After upgrading to ESXi 7.0 Update 2 and later, a virtual machine might not discover some USB devices attached to it, such as an Eaton USB UPS, and fail to communicate with the device properly.
- If you clone a VM, including the guest customization specs, move the VMDK file to another datastore and make it thick provisioned, and then power on the VM, the guest OS customization might not be preserved. In the hostd logs, you see an Event Type Description such as `The customization component failed to set the required parameters inside the guest operating system.`
  The issue occurs because while moving the VMDK file of the cloned VM to another datastore, the new `pathName` for the guest OS customization might temporarily be the same as the `oldPathName` and the package gets deleted.
- Improper sizing of the resource needs for the hostd service on an ESXi host might cause some virtual machine-related tasks to fail when you use vSphere APIs for I/O Filtering (VAIO) for VMware or third-party backup applications. For example, when a VAIO filter is attached to one or more virtual disks of a virtual machine, such VMs might fail to perform backups or power-on after a backup.
- A rare file corruption issue might occur when multiple ESXi hosts do a simultaneous file append operation on an NFSv3 datastore. As a result, if you use the Govc open source command-line utility to perform administrative actions on a vCenter instance, you might see reports with inconsistent values. For example, if you run the command `govc disk.ls` to list all FCDs in a newly created datastore, you see a different number of disks from what you expect.
- In rare cases, when a VMFS volume is closed immediately after it is opened, one of the threads in the opening process might race with a thread in the closing process and take a rare error handling path that can exit without unlocking a locked spinlock. As a result, the ESXi host might fail with a purple diagnostic screen with a message in the backtrace such as: `@BlueScreen: VERIFY bora/vmkernel/sched/cpusched.c:11154.`
- Due to reservation conflicts, WSFC applications might lose connectivity to a virtual volume-based disk after a rebind operation on that disk.
- In rare situations, the management agent that vSphere HA deploys on ESXi hosts, Fault Domain Manager (FDM), might fail to acquire a vSAN datastore in the first attempt before an exceptional condition, such as power outage, occurs. As a result, vSphere HA failover for virtual machines on that datastore might not be successful. In the vSphere Client, you see a message such as `This virtual machine failed to become vSphere HA Protected and HA may not attempt to restart it after a failure.` Successive attempts of FDM to acquire the vSAN datastore might also fail.
- In the sustainability metrics in VMware vRealize Operations, you might see the value of **Power|Total Energy (Wh)** per virtual machine higher than the ESXi host on which the VM is hosted. The issue occurs because after measuring the total energy consumed by the VM, the **power.energy** performance counter is calculated and reported in millijoules instead of joules.
- In ESXi hosts running on AMD processors, Windows virtual machines of hardware version 19 with VBS enabled might fail with a blue diagnostic screen due to a processor mode misconfiguration error. In the `vmware.log` file, you see errors such as `vcpu-0 - WinBSOD: Synthetic MSR[0xx0000x00] 0xxxx.`
- Due to an internal error, even if a CPU model is listed as supported in the VMware Compatibility Guide, in the vSphere Client you might see a warning such as `The CPU on the host is not supported by the image` during a

compliance scan by using a vSphere Lifecycle Manager image. The warning does not prevent you from completing an update or upgrade.
- When you migrate virtual machines with VBS enabled that reside on ESXi hosts running on AMD processors, such VMs might fail with a blue diagnostic screen on the target host due to a guest interruptibility state error.
- When you override a networking policy such as Teaming, Security, or Shaping for a port group, and then revert the change, after a reboot of the ESXi host, you might still see the override setting. For example, if you accept promiscuous mode activation on a port group level, then revert the mode back to Reject, and reboot the ESXi host, the setting is still Accept.
- Your remote web server might contain an HTML form field that has an input of type `password` and `username` where the `autocomplete` attribute is not set to `off` . As a result, you might see a warning by security scanners such as `AutoComplete Attribute Not Disabled for Password in Form Based Authentication` . The setting of the `autocomplete` attribute to `on` does not directly put a risk on web servers, but in certain browsers, user credentials in such forms might be saved and potentially lead to a loss of confidentiality.
- vSAN Distributed File System (vDFS) objects do not support IOPS limit. You cannot set the IOPS limit for vSAN file service objects.
- In vSphere Client, when you navigate to **Configure** > **Hardware** > **Overview**, for some servers you do not see any asset tag listed.
- When you upgrade a vSAN host from a pre-6.2 release to 7.0 or later, the VMkernel port tagging for vSAN might be lost. If this occurs, vSAN networking configuration is missing after the upgrade.
- You cannot enable vSAN File Service if the vCenter does not have Internet access.
- In rare cases, when a data breakpoint is enabled in the guest OS of virtual machines, during checkpoint resume or after a vSphere vMotion migration, an internal virtualization data structure might be accessed before it is allocated. As a result, the virtual machines crash with core dump and an error such as: vcpu-1:VMM fault 14: src=MONITOR rip=0xffffffffc0XXe00 regs=0xffffffffcXXXdc0 LBR stack=0xffffffffcXXXaXX.
- When NICs using the `ntg3` driver such as Broadcom BCM5719 and BCM5720 are connected to certain models of Dell switches, including but not limited to S4128T-ON and S3048-ON, such NICs might incorrectly drop some of the received packets greater than 6700 bytes. This might cause very low network performance or loss of connectivity.
- In case of an extended header format in the NVMe to SCSI translation layer, third-party multipathing plug-ins such as PowerPath might not account for the extended header size of 4 bytes. As a result, in the `vmkernel.log` , you see an `Invalid length RTPG Descriptor` warning.
- When installing ESXi or creating a VMFS datastore on an NVMe device, the native NVMe driver might need to handle a Compare and Write fused operation. According to NVMe specs, the Compare and Write commands must be inserted next to each other in the same Submission Queue, and the Submission Queue Tail doorbell pointer update must indicate both commands as part of one doorbell update. The native NVMe driver puts the two commands together in one Submission Queue, but writes the doorbell for each command separately. As a result, the device firmware might complete the fused commands with an error and fail to create a VMFS datastore. Since creating a VMFS datastore on a device is a prerequisite for successful ESXi installation, you might not be able to install ESXi on such NVMe devices.
- If the vSAN health check indicates that an NVMe device cannot be identified, the warning might not be cleared after you correctly select the device model.

ESXi-7.0U3l-21422485-standard

Profile Name	ESXi-7.0U3l-21422485-standard
Build	For build information, see Patches Contained in this Release.
Vendor	VMware, Inc.
Release Date	March 30, 2023
Acceptance Level	PartnerSupported
Affected Hardware	N/A
Affected Software	N/A

PRs Fixed	3091480
Related CVE numbers	CVE-2023-1017, CVE-2023-1018

This patch updates the following issues:

- The Python package is updated to versions 3.8.16/3.5.10.
- The ESXi userworld libxml2 library is updated to version 2.10.3.
- The cURL library is updated to version 7.86.0.
- The Expat XML parser is updated to version 2.5.0.
- The SQLite database is updated to version 3.40.1.
- The zlib library is updated to 1.2.13.

- The following VMware Tools ISO images are bundled with ESXi 7.0 Update 3l:
  - **windows.iso**: VMware Tools 12.1.5 supports Windows 7 SP1 or Windows Server 2008 R2 SP1 and later.
  - **linux.iso**: VMware Tools 10.3.25 ISO image for Linux OS with **glibc** 2.11 or later.

  The following VMware Tools ISO images are available for download:
  - VMware Tools 11.0.6:
    - **windows.iso**: for Windows Vista (SP2) and Windows Server 2008 Service Pack 2 (SP2).
  - VMware Tools 10.0.12:
    - **winPreVista.iso**: for Windows 2000, Windows XP, and Windows 2003.
    - **linuxPreGLibc25.iso**: supports Linux guest operating systems earlier than Red Hat Enterprise Linux (RHEL) 5, SUSE Linux Enterprise Server (SLES) 11, Ubuntu 7.04, and other distributions with **glibc** version earlier than 2.5.
  - **solaris.iso**: VMware Tools image 10.3.10 for Solaris.
  - **darwin.iso**: Supports Mac OS X versions 10.11 and later. VMware Tools 12.1.0 was the last regular release for macOS. Refer VMware knowledge base article 88698 for details.

  Follow the procedures listed in the following documents to download VMware Tools for platforms not bundled with ESXi:
  - Updating VMware Tools
  - VMware Tools for hosts provisioned with Auto Deploy
  - What Every vSphere Admin Must Know About VMware Tools
  - Earlier versions of VMware Tools
  - VMware Tools 12.1.5 Release Notes

PRs Fixed	3091480
Related CVE numbers	CVE-2023-1017, CVE-2023-1018

Known Issues

Installation, Upgrade and Migration Issues

Corrupted VFAT partitions from a vSphere 6.7 environment might cause upgrades to ESXi 7.x to fail

Due to corrupted VFAT partitions from a vSphere 6.7 environment, repartitioning the boot disks of an ESXi host might fail during an upgrade to ESXi 7.x. As a result, you might see the following errors:When upgrading to ESXi 7.0 Update 3l, the operation fails with a purple diagnostic screen and/or an error such as:

- **An error occurred while backing up VFAT partition files before re-partitioning: Failed to calculate size for temporary Ramdisk: <error>** .
- **An error occurred while backing up VFAT partition files before re-partitioning: Failed to copy files to Ramdisk: <error>** .

  If you use an ISO installer, you see the errors, but no purple diagnostic screen.

When upgrading to an ESXi 7.x version earlier than 7.0 Update 3l, you might see:

- Logs such as **ramdisk (root) is full** in the **vmkwarning.log** file.
- Unexpected rollback to ESXi 6.5 or 6.7 on reboot.
- The **/bootbank**,**/altbootbank**, and ESX-OSData partitions are not present.

Workaround: You must first remediate the corrupted partitions before completing the upgrade to ESXi 7.x. For more details, see VMware knowledge base article 91136.

After upgrading the ntg3 driver to version 4.1.9.0-4vmw, Broadcom NICs with fiber physical connectivity might lose network

Changes in the **ntg3** driver version **4.1.9.0-4vmw** might cause link issues for the fiber physical layer and connectivity on some NICs, such as Broadcom 1Gb, fails to come up.

Workaround: See VMware knowledge base article 92035.

After an upgrade to ESXi 7.0 Update 3l, some ESXi hosts and virtual machines connected to virtual switches might lose network

After an upgrade to ESXi 7.0 Update 3l, some ESXi hosts, their VMs, and other VMkernel ports, such as ports used by vSAN and vSphere Replication, which are connected to virtual switches, might lose connectivity due to an unexpected change in the NIC teaming policy. For example, the teaming policy on a portgroup might change to **Route Based on Originating Virtual Port** from **Route Based on IP Hash**. As a result, such a portgroup might lose network connectivity and some ESXi hosts and their VMs become inaccessible.

Workaround: See VMware knowledge base article 91887.

Known Issues from Previous Releases

The earlier known issues are grouped as follows.

- vSAN Issues
- vSphere Cluster Services Issues
- Installation, Upgrade, and Migration Issues
- Security Features Issues
- Networking Issues
- Storage Issues
- vCenter Server and vSphere Client Issues
- Virtual Machine Management Issues
- vSphere HA and Fault Tolerance Issues
- vSphere Lifecycle Manager Issues
- Miscellaneous Issues
- vSphere Client Issues

vSAN Issues

If you change the preferred site in a VMware vSAN Stretched Cluster, some objects might incorrectly appear as compliant

If you change the preferred site in a stretched cluster, some objects might incorrectly appear as compliant, because their policy settings might not automatically change. For example, if you configure a virtual machine to keep data at the preferred site, when you change the preferred site, data might remain on the nonpreferred site.

Workaround: Before you change a preferred site, in Advanced Settings, lower the `ClomMaxCrawlCycleMinutes` setting to 15 min to make sure objects policies are updated. After the change, revert the `ClomMaxCrawlCycleMinutes` option to the earlier value.

vSphere Cluster Services Issues

You see compatibility issues in new vCLS VMs deployed in vSphere 7.0 Update 3 environment

The default name for new vCLS VMs deployed in vSphere 7.0 Update 3 environment uses the pattern vCLS-UUID. vCLS VMs created in earlier vCenter Server versions continue to use the pattern vCLS (n). Since the use of parenthesis () is not supported by many solutions that interoperate with vSphere, you might see compatibility issues.

Workaround: Reconfigure vCLS by using retreat mode after updating to vSphere 7.0 Update 3.

Installation, Upgrade, and Migration Issues

The vCenter Upgrade/Migration pre-checks fail with "Unexpected error 87"

The vCenter Server Upgrade/Migration pre-checks fail when the Security Token Service (STS) certificate does not contain a Subject Alternative Name (SAN) field. This situation occurs when you have replaced the vCenter 5.5 Single Sign-On certificate with a custom certificate that has no SAN field, and you attempt to upgrade to vCenter Server 7.0. The upgrade considers the STS certificate invalid and the pre-checks prevent the upgrade process from continuing.

Workaround: Replace the STS certificate with a valid certificate that contains a SAN field then proceed with the vCenter Server 7.0 Upgrade/Migration.

Problems upgrading to vSphere 7.0 with pre-existing CIM providers

After upgrade, previously installed 32-bit CIM providers stop working because ESXi requires 64-bit CIM providers. Customers may lose management API functions related to CIMPDK, NDDK (native DDK), HEXDK, VAIODK (IO filters), and see errors related to **uwglibc** dependency.

The syslog reports module missing, "32 bit shared libraries not loaded."

Workaround: There is no workaround. The fix is to download new 64-bit CIM providers from your vendor.

Installation of 7.0 Update 1 drivers on ESXi 7.0 hosts might fail

You cannot install drivers applicable to ESXi 7.0 Update 1 on hosts that run ESXi 7.0 or 7.0b.

The operation fails with an error, such as:

```
VMW_bootbank_qedrntv_3.40.4.0-12vmw.701.0.0.xxxxxxx requires vmkapi_2_7_0_0, but the requirement cannot be satisfied within the ImageProfile. Please refer to the log file for more details.
```

Workaround: Update the ESXi host to 7.0 Update 1. Retry the driver installation.

UEFI booting of ESXi hosts might stop with an error during an update to ESXi 7.0 Update 2 from an earlier version of ESXi 7.0

If you attempt to update your environment to 7.0 Update 2 from an earlier version of ESXi 7.0by using vSphere Lifecycle Manager patch baselines, UEFI booting of ESXi hosts might stop with an error such as:

```
Loading /boot.cfgFailed to load crypto64.efiFatal error: 15 (Not found)
```

Workaround: For more information, see VMware knowledge base articles 83063 and 83107 .

If legacy VIBs are in use on an ESXi host, vSphere Lifecycle Manager cannot extract a desired software specification to seed to a new cluster

With vCenter Server 7.0 Update 2, you can create a new cluster by importing the desired software specification from a single reference host. However, if legacy VIBs are in use on an ESXi host, vSphere Lifecycle Manager cannot extract in the vCenter Server instance where you create the cluster a reference software specification from such a host. In the `/var/log/lifecycle.log` , you see messages such as:

```
020-11-11T06:54:03Z lifecycle: 1000082644: HostSeeding:499
ERROR Extract depot failed: Checksum doesn't match. Calculated
5b404e28e83b1387841bb417da93c8c796ef2497c8af0f79583fd54e789d8826, expected:
0947542e30b794c721e21fb595f1851b247711d0619c55489a6a8cae6675e796 2020-11-11T06:54:04Z
lifecycle: 1000082644: imagemanagerctl:366 ERROR Extract depot failed.
2020-11-11T06:54:04Z lifecycle: 1000082644: imagemanagerctl:145 ERROR [VibChecksumError]
```

Workaround: Follow the steps described in VMware knowledge base article 83042.

You see a short burst of log messages in the syslog.log after every ESXi boot

After updating to ESXi 7.0 Update 2, you might see a short burst of log messages after every ESXi boot.

Such logs do not indicate any issue with ESXi and you can ignore these messages. For example:

```
2021-01-19T22:44:22Z watchdog-vaai-nasd: '/usr/lib/vmware/nfs/bin/vaai-nasd -f'
exited after 0 seconds (quick failure 127) 12021-01-19T22:44:22Z watchdog-vaai-
nasd: Executing '/usr/lib/vmware/nfs/bin/vaai-nasd -f'2021-01-19T22:44:22.990Z
aainasd[1000051135]: Log for VAAI-NAS Daemon for NFS version=1.0 build=build-00000

vaainasd[1000051135]: Switching to VMware syslog extensions2021-01-19T22:44:22.992Z
vaainasd[1000051135]: Loading VAAI-NAS plugin(s).2021-01-19T22:44:22.992Z
vaainasd[1000051135]: DISKLIB-PLUGIN : Not loading plugin /usr/lib/vmware/nas_plugins/
lib64: Not a shared library.
```

Workaround: None

You see warning messages for missing VIBs in vSphere Quick Boot compatibility check reports

After you upgrade to ESXi 7.0 Update 2, if you check vSphere Quick Boot compatibility of your environment by using the `/usr/lib/vmware/loadesx/bin/loadESXCheckCompat.py` command, you might see some warning messages for missing VIBs in the shell. For example:

```
Cannot find VIB(s) ... in the given VIB collection.Ignoring missing reserved VIB(s) ...,
they are removed from reserved VIB IDs.
```

Such warnings do not indicate a compatibility issue.

Workaround: The missing VIB messages can be safely ignored and do not affect the reporting of vSphere Quick Boot compatibility. The final output line of the `loadESXCheckCompat` command unambiguously indicates if the host is compatible.

Auto bootstrapping a cluster that you manage with a vSphere Lifecycle Manager image fails with an error

If you attempt auto bootstrapping a cluster that you manage with a vSphere Lifecycle Manager image to perform a stateful install and overwrite the VMFS partitions, the operation fails with an error. In the support bundle, you see messages such as:

```
2021-02-11T19:37:43Z Host Profiles[265671 opID=MainThread]: ERROR:
EngineModule::ApplyHostConfig. Exception: [Errno 30] Read-only file system
```

Workaround: Follow vendor guidance to clean the VMFS partition in the target host and retry the operation. Alternatively, use an empty disk. For more information on the disk-partitioning utility on ESXi, see VMware knowledge base article 1036609.

Upgrades to ESXi 7.x from 6.5.x and 6.7.0 by using ESXCLI might fail due to a space limitation

Upgrades to ESXi 7.x from 6.5.x and 6.7.0 by using the `esxcli software profile update` or `esxcli software profile install` ESXCLI commands might fail, because the ESXi bootbank might be less than the size of the image profile. In the ESXi Shell or the PowerCLI shell, you see an error such as:

```
[InstallationError]
The pending transaction requires 244 MB free space, however the maximum supported size is 239 MB.
```

```
Please refer to the log file for more details.
```

The issue also occurs when you attempt an ESXi host upgrade by using the ESXCLI commands `esxcli software vib update` or `esxcli software vib install`.

Workaround: You can perform the upgrade in two steps, by using the `esxcli software profile update` command to update ESXi hosts to ESXi 6.7 Update 1 or later, and then update to 7.0 Update 1c. Alternatively, you can run an upgrade by using an ISO image and the vSphere Lifecycle Manager.

You cannot migrate linked clones across vCenter Servers

If you migrate a linked clone across vCenter Servers, operations such as power on and delete might fail for the source virtual machine with an `Invalid virtual machine state` error.

Workaround: Keep linked clones on the same vCenter Server as the source VM. Alternatively, promote the linked clone to full clone before migration.

Migration across vCenter Servers of virtual machines with many virtual disks and snapshot levels to a datastore on NVMe over TCP storage might fail

Migration across vCenter Servers of virtual machines with more than 180 virtual disks and 32 snapshot levels to a datastore on NVMe over TCP storage might fail. The ESXi host preemptively fails with an error such as `The migration has exceeded the maximum switchover time of 100 second(s).`

Workaround: None

A virtual machine with enabled Virtual Performance Monitoring Counters (VPMC) might fail to migrate between ESXi hosts

If you try to migrate a virtual machine with enabled VPMC by using vSphere vMotion, the operation might fail if the target host is using some of the counters to compute memory or performance statistics. The operation fails with an error such as `A performance counter used by the guest is not available on the host CPU.`

Workaround: Power off the virtual machine and use cold migration. For more information, see VMware knowledge base article 81191.

If a live VIB install, upgrade, or remove operation immediately precedes an interactive or scripted upgrade to ESXi 7.0 Update 3 by using the installer ISO, the upgrade fails

When a VIB install, upgrade, or remove operation immediately precedes an interactive or scripted upgrade to ESXi 7.0 Update 3 by using the installer ISO, the ConfigStore might not keep some configurations of the upgrade. As a result, ESXi hosts become inaccessible after the upgrade operation, although the upgrade seems successful. To prevent this issue, the ESXi 7.0 Update 3 installer adds a temporary check to block such scenarios. In the ESXi installer console, you see the following error message: `Live VIB installation, upgrade or removal may cause subsequent ESXi upgrade to fail when using the ISO installer.`

Workaround: Use an alternative upgrade method to avoid the issue, such as using ESXCLI or the vSphere Lifecycle Manager.

Smart Card and RSA SecurID authentication might stop working after upgrading to vCenter Server 7.0

If you have configured vCenter Server for either Smart Card or RSA SecurID authentication, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057 before starting the vSphere 7.0 upgrade process. If you do not perform the workaround as described in the KB, you might see the following error messages and Smart Card or RSA SecurID authentication does not work.

"Smart card authentication may stop working. Smart card settings may not be preserved, and smart card authentication may stop working."

or

"RSA SecurID authentication may stop working. RSA SecurID settings may not be preserved, and RSA SecurID authentication may stop working."

Workaround: Before upgrading to vSphere 7.0, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057.

The vlanid property in custom installation scripts might not work

If you use a custom installation script that sets the `vlanid` property to specify a desired VLAN, the property might not take effect on newly installed ESXi hosts. The issue occurs only when a physical NIC is already connected to DHCP when the installation starts. The `vlanid` property works properly when you use a newly connected NIC.

Workaround: Manually set the VLAN from the Direct Console User Interface after you boot the ESXi host. Alternatively, disable the physical NIC and then boot the host.

HPE servers with Trusted Platform Module (TPM) boot, but remote attestation fails

Some HPE servers do not have enough event log space to properly finish TPM remote attestation. As a result, the VMkernel boots, but remote attestation fails due to the truncated log.

Workaround: None.

Upgrading a vCenter Server with an external Platform Services Controller from 6.7u3 to 7.0 fails with VMAFD error

When you upgrade a vCenter Server deployment using an external Platform Services Controller, you converge the Platform Services Controller into a vCenter Server appliance. If the upgrade fails with the error `install.vmafd.vmdir_vdcpromo_error_21` , the VMAFD firstboot process has failed. The VMAFD firstboot process copies the VMware Directory Service Database (data.mdb) from the source Platform Services Controller and replication partner vCenter Server appliance.

Workaround: Disable TCP Segmentation Offload (TSO) and Generic Segmentation Offload (GSO) on the Ethernet adapter of the source Platform Services Controller or replication partner vCenter Server appliance before upgrading a vCenter Server with an external Platform Services Controller. See Knowledge Base article: https://kb.vmware.com/s/article/74678

Smart card and RSA SecurID settings may not be preserved during vCenter Server upgrade

Authentication using RSA SecurID will not work after upgrading to vCenter Server 7.0. An error message will alert you to this issue when attempting to login using your RSA SecurID login.

Workaround: Reconfigure the smart card or RSA SecureID.

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with network error message

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with the error message `IP already exists in the network`. This prevents the migration process from configuring the network parameters on the new vCenter Server appliance. For more information, examine the log file: `/var/log/vmware/upgrade/UpgradeRunner.log`

Workaround:

1. Verify that all Windows Updates have been completed on the source vCenter Server for Windows instance, or disable automatic Windows Updates until after the migration finishes.
2. Retry the migration of vCenter Server for Windows to vCenter Server appliance 7.0.

When you configure the number of virtual functions for an SR-IOV device by using the max_vfs module parameter, the changes might not take effect

In vSphere 7.0, you can configure the number of virtual functions for an SR-IOV device by using the Virtual Infrastructure Management (VIM) API, for example, through the vSphere Client. The task does not require reboot of the ESXi host. After you use the VIM API configuration, if you try to configure the number of SR-IOV virtual functions by using the `max_vfs` module parameter, the changes might not take effect because they are overridden by the VIM API configuration.

Workaround: None. To configure the number of virtual functions for an SR-IOV device, use the same method every time. Use the VIM API or use the `max_vfs` module parameter and reboot the ESXi host.

Upgraded vCenter Server appliance instance does not retain all the secondary networks (NICs) from the source instance

During a major upgrade, if the source instance of the vCenter Server appliance is configured with multiple secondary networks other than the VCHA NIC, the target vCenter Server instance will not retain secondary networks other than the VCHA NIC. If the source instance is configured with multiple NICs that are part of VDS port groups, the NIC configuration will not be preserved during the upgrade. Configurations for vCenter Server appliance instances that are part of the standard port group will be preserved.

Workaround: None. Manually configure the secondary network in the target vCenter Server appliance instance.

After upgrading or migrating a vCenter Server with an external Platform Services Controller, users authenticating using Active Directory lose access to the newly upgraded vCenter Server instance

After upgrading or migrating a vCenter Server with an external Platform Services Controller, if the newly upgraded vCenter Server is not joined to an Active Directory domain, users authenticating using Active Directory will lose access to the vCenter Server instance.

Workaround: Verify that the new vCenter Server instance has been joined to an Active Directory domain. See Knowledge Base article: https://kb.vmware.com/s/article/2118543

Migrating a vCenter Server for Windows with an external Platform Services Controller using an Oracle database fails

If there are non-ASCII strings in the Oracle events and tasks table the migration can fail when exporting events and tasks data. The following error message is provided: UnicodeDecodeError

Workaround: None.

After an ESXi host upgrade, a Host Profile compliance check shows non-compliant status while host remediation tasks fail

The non-compliant status indicates an inconsistency between the profile and the host.

This inconsistency might occur because ESXi 7.0 does not allow duplicate claim rules, but the profile you use contains duplicate rules. For example, if you attempt to use the Host Profile that you extracted from the host before upgrading ESXi 6.5 or ESXi 6.7 to version 7.0 and the Host Profile contains any duplicate claim rules of system default rules, you might experience the problems.

Workaround:

1. Remove any duplicate claim rules of the system default rules from the Host Profile document.
2. Check the compliance status.
3. Remediate the host.
4. If the previous steps do not help, reboot the host.

Error message displays in the vCenter Server Management Interface

After installing or upgrading to vCenter Server 7.0, when you navigate to the Update panel within the vCenter Server Management Interface, the error message "Check the URL and try again" displays. The error message does not prevent you from using the functions within the Update panel, and you can view, stage, and install any available updates.

Workaround: None.

Security Features Issues

Turn off the Service Location Protocol service in ESXi, slpd, to prevent potential security vulnerabilities

Some services in ESXi that run on top of the host operating system, including slpd, the CIM object broker, sfcbd, and the related openwsmand service, have proven security vulnerabilities. VMware has addressed all known vulnerabilities in VMSA-2019-0022 and VMSA-2020-0023, and the fixes are part of the vSphere 7.0 Update 2 release. While sfcbd and openwsmand are disabled by default in ESXi, slpd is enabled by default and you must turn it off, if not necessary, to prevent exposure to a future vulnerability after an upgrade.

Workaround: To turn off the slpd service, run the following PowerCLI commands:

```
$ Get-VMHost | Get-VmHostService | Where-Object {$_.key -eq "slpd"} | Set-VMHostService -policy "off"$ Get-VMHost | Get-VmHostService | Where-Object {$_.key -eq "slpd"} | Stop-VMHostService -Confirm:$false
```

Alternatively, you can use the command `chkconfig slpd off && /etc/init.d/slpd stop`.

The openwsmand service is not on the ESXi services list and you can check the service state by using the following PowerCLI commands:

```
$esx=(Get-EsxCli -vmhost xx.xx.xx.xx -v2)$esx.system.process.list.invoke() | where CommandLine -like '*openwsman*' | select commandline
```

In the ESXi services list, the sfcbd service appears as sfcbd-watchdog.

For more information, see VMware knowledge base articles 76372 and 1025757.

Encrypted virtual machine fails to power on when HA-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled HA on the Trusted Cluster and one or more hosts in the cluster fails attestation, an encrypted virtual machine cannot power on.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Encrypted virtual machine fails to power on when DRS-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled DRS on the Trusted Cluster and one or more hosts in the cluster fails attestation, DRS might try to power on an encrypted virtual machine on an unattested host in the cluster. This operation puts the virtual machine in a locked state.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Migrating or cloning encrypted virtual machines across vCenter Server instances fails when attempting to do so using the vSphere Client

If you try to migrate or clone an encrypted virtual machine across vCenter Server instances using the vSphere Client, the operation fails with the following error message: "The operation is not allowed in the current state."

Workaround: You must use the vSphere APIs to migrate or clone encrypted virtual machines across vCenter Server instances.

Networking Issues

Reduced throughput in networking performance on Intel 82599/X540/X550 NICs

The new queue-pair feature added to ixgben driver to improve networking performance on Intel 82599EB/X540/X550 series NICs might reduce throughput under some workloads in vSphere 7.0 as compared to vSphere 6.7.

Workaround: To achieve the same networking performance as vSphere 6.7, you can disable the queue-pair with a module parameter. To disable the queue-pair, run the command:

```
# esxcli system module parameters set -p "QPair=0,0,0,0..." -m ixgben
```

After running the command, reboot.

One or more I/O devices do not generate interrupts when the AMD IOMMU is in use

If the I/O devices on your ESXi host provide more than a total of 512 distinct interrupt sources, some sources are erroneously assigned an interrupt-remapping table entry (IRTE) index in the AMD IOMMU that is greater than the maximum value. Interrupts from such a source are lost, so the corresponding I/O device behaves as if interrupts are disabled.

Workaround: Use the ESXCLI command `esxcli system settings kernel set -s iovDisableIR -v true` to disable the AMD IOMMU interrupt remapper. Reboot the ESXi host so that the command takes effect.

When you set auto-negotiation on a network adapter, the device might fail

In some environments, if you set link speed to auto-negotiation for network adapters by using the command `esxcli network nic set -a -n vmmicx`, the devices might fail and reboot does not recover connectivity. The issue is specific to a combination of some Intel X710/X722 network adapters, a SFP+ module and a physical switch, where auto-negotiate speed/duplex scenario is not supported.

Workaround: Make sure you use an Intel-branded SFP+ module. Alternatively, use a Direct Attach Copper (DAC) cable.

Solarflare x2542 and x2541 network adapters configured in 1x100G port mode achieve throughput of up to 70Gbps in a vSphere environment

vSphere 7.0 Update 2 supports Solarflare x2542 and x2541 network adapters configured in 1x100G port mode. However, you might see a hardware limitation in the devices that causes the actual throughput to be up to some 70Gbps in a vSphere environment.

Workaround: None

VLAN traffic might fail after a NIC reset

A NIC with PCI device ID 8086:1537 might stop to send and receive VLAN tagged packets after a reset, for example, with a command `vsish -e set /net/pNics/vmnic0/reset 1`.

Workaround: Avoid resetting the NIC. If you already face the issue, use the following commands to restore the VLAN capability, for example at vmnic0:

```
# esxcli network nic software set --tagging=1 -n vmnic0# esxcli network nic software set --tagging=0 -n vmnic0
```

Any change in the NetQueue balancer settings causes NetQueue to be disabled after an ESXi host reboot

Any change in the NetQueue balancer settings by using the command `esxcli/localcli network nic queue loadbalancer set -n <nicname> --<lb_setting>` causes NetQueue, which is enabled by default, to be disabled after an ESXi host reboot.

Workaround: After a change in the NetQueue balancer settings and host reboot, use the command `configstorecli config current get -c esx -g network -k nics` to retrieve ConfigStore data to verify whether the `/esx/network/nics/net_queue/load_balancer/enable` is working as expected.

After you run the command, you see output similar to:

```
{"mac": "02:00:0e:6d:14:3e","name": "vmnic1","net_queue": { "load_balancer":
{ "dynamic_pool": true, "enable": true }},"virtual_mac": "00:50:56:5a:21:11"}
```

If the output is not as expected, for example `"load_balancer": "enable": false"` , run the following command:

```
esxcli/localcli network nic queue loadbalancer state set -n <nicname> -e true
```

Paravirtual RDMA (PVRDMA) network adapters do not support NSX networking policies

If you configure an NSX distributed virtual port for use in PVRDMA traffic, the RDMA protocol traffic over the PVRDMA network adapters does not comply with the NSX network policies.

Workaround: Do not configure NSX distributed virtual ports for use in PVRDMA traffic.

Rollback from converged vSphere Distributed Switch (VDS) to NSX-T VDS is not supported in vSphere 7.0 Update 3

Rollback from converged VDS that supports both vSphere 7 traffic and NSX-T 3 traffic on the same VDS to one N-VDS for NSX-T traffic is not supported in vSphere 7.0 Update 3.

Workaround: None

If you do not set the nmlx5 network driver module parameter, network connectivity or ESXi hosts might fail

If you do not set the `supported_num_ports` module parameter for the `nmlx5_core` driver on an ESXi host with multiple network adapters of versions Mellanox ConnectX-4, Mellanox ConnectX-5 and Mellanox ConnectX-6, the driver might not allocate sufficient memory for operating all the NIC ports for the host. As a result, you might experience network loss or ESXi host failure with purple diagnostic screen, or both.

Workaround: Set the `supported_num_ports` module parameter value in the `nmlx5_core` network driver equal to the total number of Mellanox ConnectX-4, Mellanox ConnectX-5 and Mellanox ConnectX-6 network adapter ports on the ESXi host.

High throughput virtual machines may experience degradation in network performance when Network I/O Control (NetIOC) is enabled

Virtual machines requiring high network throughput can experience throughput degradation when upgrading from vSphere 6.7 to vSphere 7.0 with NetIOC enabled.

Workaround: Adjust the `ethernetx.ctxPerDev` setting to enable multiple worlds.

IPv6 traffic fails to pass through VMkernel ports using IPsec

When you migrate VMkernel ports from one port group to another, IPv6 traffic does not pass through VMkernel ports using IPsec.

Workaround: Remove the IPsec security association (SA) from the affected server, and then reapply the SA. To learn how to set and remove an IPsec SA, see the *vSphere Security* documentation.

Higher ESX network performance with a portion of CPU usage increase

ESX network performance may increase with a portion of CPU usage.

Workaround: Remove and add the network interface with only 1 rx dispatch queue. For example:

```
esxcli network ip interface remove --interface-name=vmk1
esxcli network ip interface add --interface-name=vmk1 --num-rxqueue=1
```

VM might lose Ethernet traffic after hot-add, hot-remove or storage vMotion

A VM might stop receiving Ethernet traffic after a hot-add, hot-remove or storage vMotion. This issue affects VMs where the uplink of the VNIC has SR-IOV enabled. PVRDMA virtual NIC exhibits this issue when the uplink of the virtual network is a Mellanox RDMA capable NIC and RDMA namespaces are configured.

Workaround: You can hot-remove and hot-add the affected Ethernet NICs of the VM to restore traffic. On Linux guest operating systems, restarting the network might also resolve the issue. If these workarounds have no effect, you can reboot the VM to restore network connectivity.

Change of IP address for a VCSA deployed with static IP address requires that you create the DNS records in advance

With the introduction of the DDNS, the DNS record update only works for VCSA deployed with DHCP configured networking. While changing the IP address of the vCenter server via VAMI, the following error is displayed:

The specified IP address does not resolve to the specified hostname.

Workaround: There are two possible workarounds.

1. Create an additional DNS entry with the same FQDN and desired IP address. Log in to the VAMI and follow the steps to change the IP address.
2. Log in to the VCSA using ssh. Execute the following script:
   `./opt/vmware/share/vami/vami_config_net`
   Use option 6 to change the IP adddress of eth0. Once changed, execute the following script:
   `./opt/likewise/bin/lw-update-dns`
   Restart all the services on the VCSA to update the IP information on the DNS server.

It may take several seconds for the NSX Distributed Virtual Port Group (NSX DVPG) to be removed after deleting the corresponding logical switch in NSX Manager.

As the number of logical switches increases, it may take more time for the NSX DVPG in vCenter Server to be removed after deleting the corresponding logical switch in NSX Manager. In an environment with 12000 logical switches, it takes approximately 10 seconds for an NSX DVPG to be deleted from vCenter Server.

Workaround: None.

Hostd runs out of memory and fails if a large number of NSX Distributed Virtual port groups are created.

In vSphere 7.0, NSX Distributed Virtual port groups consume significantly larger amounts of memory than opaque networks. For this reason, NSX Distributed Virtual port groups can not support the same scale as an opaque network given the same amount of memory.

Workaround:To support the use of NSX Distributed Virtual port groups, increase the amount of memory in your ESXi hosts. If you verify that your system has adequate memory to support your VMs, you can directly increase the memory of `hostd` using the following command.

```
localcli --plugin-dir /usr/lib/vmware/esxcli/int/ sched group setmemconfig --group-path
host/vim/vmvisor/hostd --units mb --min 2048 --max 2048
```

Note that this will cause `hostd` to use memory normally reserved for your environment's VMs. This may have the affect of reducing the number of VMs your ESXi host can support.

DRS may incorrectly launch vMotion if the network reservation is configured on a VM

If the network reservation is configured on a VM, it is expected that DRS only migrates the VM to a host that meets the specified requirements. In a cluster with NSX transport nodes, if some of the transport nodes join the transport zone by NSX-T Virtual Distributed Switch (N-VDS), and others by vSphere Distributed Switch (VDS) 7.0, DRS may incorrectly launch vMotion. You might encounter this issue when:

- The VM connects to an NSX logical switch configured with a network reservation.
- Some transport nodes join transport zone using N-VDS, and others by VDS 7.0, or, transport nodes join the transport zone through different VDS 7.0 instances.

Workaround: Make all transport nodes join the transport zone by N-VDS or the same VDS 7.0 instance.

When adding a VMkernel NIC (vmknic) to an NSX portgroup, vCenter Server reports the error "Connecting VMKernel adapter to a NSX Portgroup on a Stateless host is not a supported operation. Please use Distributed Port Group instead."

- For stateless ESXi on Distributed Virtual Switch (VDS), the vmknic on a NSX port group is blocked. You must instead use a Distributed Port Group.
- For stateful ESXi on VDS, vmknic on NSX port group is supported, but vSAN may have an issue if it is using vmknic on a NSX port group.

Workaround: Use a Distributed Port Group on the same VDS.

Enabling SRIOV from vCenter for QLogic 4x10GE QL41164HFCU CNA might fail

If you navigate to the **Edit Settings** dialog for physical network adapters and attempt to enable SR-IOV, the operation might fail when using QLogic 4x10GE QL41164HFCU CNA. Attempting to enable SR-IOV might lead to a network outage of the ESXi host.

Workaround: Use the following command on the ESXi host to enable SRIOV:

```
esxcfg-module
```

vCenter Server fails if the hosts in a cluster using Distributed Resource Scheduler (DRS) join NSX-T networking by a different Virtual Distributed Switch (VDS) or combination of NSX-T Virtual Distributed Switch (NVDS) and VDS

In vSphere 7.0, when using NSX-T networking on vSphere VDS with a DRS cluster, if the hosts do not join the NSX transport zone by the same VDS or NVDS, it can cause vCenter Server to fail.

Workaround: Have hosts in a DRS cluster join the NSX transport zone using the same VDS or NVDS.

Storage Issues

VMFS datastores are not mounted automatically after disk hot remove and hot insert on HPE Gen10 servers with SmartPQI controllers

When SATA disks on HPE Gen10 servers with SmartPQI controllers without expanders are hot removed and hot inserted back to a different disk bay of the same machine, or when multiple disks are hot removed and hot inserted back in a different order, sometimes a new local name is assigned to the disk. The VMFS datastore on that disk appears as a snapshot and will not be mounted back automatically because the device name has changed.

Workaround: None. SmartPQI controller does not support unordered hot remove and hot insert operations.

VOMA check on NVMe based VMFS datastores fails with error

VOMA check is not supported for NVMe based VMFS datastores and will fail with the error:

```
ERROR: Failed to reserve device. Function not implemented
```

Example:

```
# voma -m vmfs -f check -d /vmfs/devices/disks/: <partition#>
Running VMFS Checker version 2.1 in check mode
Initializing LVM metadata, Basic Checks will be done

Checking for filesystem activity
Performing filesystem liveness check..|Scanning for VMFS-6 host activity (4096 bytes/HB, 1024 HBs).
ERROR: Failed to reserve device. Function not implemented
Aborting VMFS volume check
VOMA failed to check device : General Error
```

Workaround: None. If you need to analyse VMFS metadata, collect it using the `-l` option, and pass to VMware customer support. The command for collecting the dump is:

```
voma -l -f dump -d /vmfs/devices/disks/:<partition#>
```

Using the VM reconfigure API to attach an encrypted First Class Disk to an encrypted virtual machine might fail with error

If an FCD and a VM are encrypted with different crypto keys, your attempts to attach the encrypted FCD to the encrypted VM using the `VM reconfigure API` might fail with the error message:

```
Cannot decrypt disk because key or password is incorrect.
```

Workaround: Use the `attachDisk API` rather than the `VM reconfigure API` to attach an encrypted FCD to an encrypted VM.

ESXi host might get in non responding state if a non-head extent of its spanned VMFS datastore enters the Permanent Device Loss (PDL) state

This problem does not occur when a non-head extent of the spanned VMFS datastore fails along with the head extent. In this case, the entire datastore becomes inaccessible and no longer allows I/Os.

In contrast, when only a non-head extent fails, but the head extent remains accessible, the datastore heartbeat appears to be normal. And the I/Os between the host and the datastore continue. However, any I/Os that depend on the failed non-head extent start failing as well. Other I/O transactions might accumulate while waiting for the failing I/Os to resolve, and cause the host to enter the non responding state.

Workaround: Fix the PDL condition of the non-head extent to resolve this issue.

Virtual NVMe Controller is the default disk controller for Windows 10 guest operating systems

The Virtual NVMe Controller is the default disk controller for the following guest operating systems when using Hardware Version 15 or later:

Windows 10

Windows Server 2016

Windows Server 2019

Some features might not be available when using a Virtual NVMe Controller. For more information, see https://kb.vmware.com/s/article/2147714

Note: Some clients use the previous default of LSI Logic SAS. This includes ESXi host client and PowerCLI.

Workaround: If you need features not available on Virtual NVMe, switch to VMware Paravirtual SCSI (PVSCSI) or LSI Logic SAS. For information on using VMware Paravirtual SCSI (PVSCSI), see https://kb.vmware.com/s/article/1010398

After an ESXi host upgrade to vSphere 7.0, presence of duplicate core claim rules might cause unexpected behavior

Claim rules determine which multipathing plugin, such as NMP, HPP, and so on, owns paths to a particular storage device. ESXi 7.0 does not support duplicate claim rules. However, the ESXi 7.0 host does not alert you if you add duplicate rules to the existing claim rules inherited through an upgrade from a legacy release. As a result of using duplicate rules, storage devices might be claimed by unintended plugins, which can cause unexpected outcome.

Workaround: Do not use duplicate core claim rules. Before adding a new claim rule, delete any existing matching claim rule.

A CNS query with the compliance status filter set might take unusually long time to complete

The CNS QueryVolume API enables you to obtain information about the CNS volumes, such as volume health and compliance status. When you check the compliance status of individual volumes, the results are obtained quickly. However, when you invoke the CNS QueryVolume API to check the compliance status of multiple volumes, several tens or hundreds, the query might perform slowly.

Workaround: Avoid using bulk queries. When you need to get compliance status, query one volume at a time or limit the number of volumes in the query API to 20 or fewer. While using the query, avoid running other CNS operations to get the best performance.

A VMFS datastore backed by an NVMe over Fabrics namespace or device might become permanently inaccessible after recovering from an APD or PDL failure

If a VMFS datastore on an ESXi host is backed by an NVMe over Fabrics namespace or device, in case of an all paths down (APD) or permanent device loss (PDL) failure, the datastore might be inaccessible even after recovery. You cannot access the datastore from either the ESXi host or the vCenter Server system.

Workaround: To recover from this state, perform a rescan on a host or cluster level. For more information, see Perform Storage Rescan.

Deleted CNS volumes might temporarily appear as existing in the CNS UI

After you delete an FCD disk that backs a CNS volume, the volume might still show up as existing in the CNS UI. However, your attempts to delete the volume fail. You might see an error message similar to the following:

```
The object or item referred to could not be found.
```

Workaround: The next full synchronization will resolve the inconsistency and correctly update the CNS UI.

Attempts to attach multiple CNS volumes to the same pod might occasionally fail with an error

When you attach multiple volumes to the same pod simultaneously, the attach operation might occasionally choose the same controller slot. As a result, only one of the operations succeeds, while other volume mounts fail.

Workaround: After Kubernetes retries the failed operation, the operation succeeds if a controller slot is available on the node VM.

Under certain circumstances, while a CNS operation fails, the task status appears as successful in the vSphere Client

This might occur when, for example, you use an incompliant storage policy to create a CNS volume. The operation fails, while the vSphere Client shows the task status as successful.

Workaround: The successful task status in the vSphere Client does not guarantee that the CNS operation succeeded. To make sure the operation succeeded, verify its results.

Unsuccessful delete operation for a CNS persistent volume might leave the volume undeleted on the vSphere datastore

This issue might occur when the CNS Delete API attempts to delete a persistent volume that is still attached to a pod. For example, when you delete the Kubernetes namespace where the pod runs. As a result, the volume gets cleared from CNS and the CNS query operation does not return the volume. However, the volume continues to reside on the datastore and cannot be deleted through the repeated CNS Delete API operations.

Workaround: None.

vCenter Server and vSphere Client Issues

Vendor providers go offline after a PNID change

When you change the vCenter IP address (PNID change), the registered vendor providers go offline.

Workaround: Re-register the vendor providers.

Cross vCenter migration of a virtual machine fails with an error

When you use cross vCenter vMotion to move a VM's storage and host to a different vCenter server instance, you might receive the error `The operation is not allowed in the current state.`

This error appears in the UI wizard after the Host Selection step and before the Datastore Selection step, in cases where the VM has an assigned storage policy containing host-based rules such as encryption or any other IO filter rule.

Workaround: Assign the VM and its disks to a storage policy without host-based rules. You might need to decrypt the VM if the source VM is encrypted. Then retry the cross vCenter vMotion action.

Storage Sensors information in Hardware Health tab shows incorrect values on vCenter UI, host UI, and MOB

When you navigate to **Host > Monitor > Hardware Health > Storage Sensors** on vCenter UI, the storage information displays either incorrect or unknown values. The same issue is observed on the host UI and the MOB path `"runtime.hardwareStatusInfo.storageStatusInfo"` as well.

Workaround: None.

vSphere UI host advanced settings shows the current product locker location as empty with an empty default

vSphere UI host advanced settings shows the current product locker location as empty with an empty default. This is inconsistent as the actual product location `symlink` is created and valid. This causes confusion to the user. The default cannot be corrected from UI.

Workaround: User can use the esxcli command on the host to correct the current product locker location default as below.

1. Remove the existing Product Locker Location setting with: `"esxcli system settings advanced remove -o ProductLockerLocation"`

2. Re-add the Product Locker Location setting with the appropriate default:

2.a. If the ESXi is a full installation, the default value is `"/locker/packages/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/locker/packages/vmtoolsRepo"`

2.b. If the ESXi is a PXEboot configuration such as autodeploy, the default value is: `"/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/vmtoolsRepo"`

Run the following command to automatically figure out the location: `export PRODUCT_LOCKER_DEFAULT=`readlink /productLocker``

Add the setting: `esxcli system settings advanced add -d "Path to VMware Tools repository" -o ProductLockerLocation -t string -s $PRODUCT_LOCKER_DEFAULT`

You can combine all the above steps in step 2 by issuing the single command:

```
esxcli system settings advanced add -d "Path to VMware Tools repository" -o
ProductLockerLocation -t string -s `readlink /productLocker`
```

Linked Software-Defined Data Center (SDDC) vCenter Server instances appear in the on-premises vSphere Client if a vCenter Cloud Gateway is linked to the SDDC.

When a vCenter Cloud Gateway is deployed in the same environment as an on-premises vCenter Server, and linked to an SDDC, the SDDC vCenter Server will appear in the on-premises vSphere Client. This is unexpected behavior and the linked SDDC vCenter Server should be ignored. All operations involving the linked SDDC vCenter Server should be performed on the vSphere Client running within the vCenter Cloud Gateway.

Workaround: None.

Virtual Machine Management Issues

UEFI HTTP booting of virtual machines on ESXi hosts of version earlier than 7.0 Update 2 fails

UEFI HTTP booting of virtual machines is supported only on hosts of version ESXi 7.0 Update 2 and later and VMs with HW version 19 or later.

Workaround: Use UEFI HTTP booting only in virtual machines with HW version 19 or later. Using HW version 19 ensures the virtual machines are placed only on hosts with ESXi version 7.0 Update 2 or later.

Virtual machine snapshot operations fail in vSphere Virtual Volumes datastores on Purity version 5.3.10

Virtual machine snapshot operations fail in vSphere Virtual Volumes datastores on Purity version 5.3.10 with an error such as `An error occurred while saving the snapshot: The VVol target encountered a vendor specific error.` The issue is specific for Purity version 5.3.10.

Workaround: Upgrade to Purity version 6.1.7 or follow vendor recommendations.

The postcustomization section of the customization script runs before the guest customization

When you run the guest customization script for a Linux guest operating system, the `precustomization` section of the customization script that is defined in the customization specification runs before the guest customization and the `postcustomization` section runs after that. If you enable Cloud-Init in the guest operating system of a virtual machine, the `postcustomization` section runs before the customization due to a known issue in Cloud-Init.

Workaround: Disable Cloud-Init and use the standard guest customization.

Group migration operations in vSphere vMotion, Storage vMotion, and vMotion without shared storage fail with error

When you perform group migration operations on VMs with multiple disks and multi-level snapshots, the operations might fail with the error `com.vmware.vc.GenericVmConfigFault Failed waiting for data. Error 195887167. Connection closed by remote host, possibly due to timeout.`

Workaround: Retry the migration operation on the failed VMs one at a time.

Deploying an OVF or OVA template from a URL fails with a 403 Forbidden error

The URLs that contain an HTTP query parameter are not supported. For example, `http://webaddress.com?file=abc.ovf` or the Amazon pre-signed S3 URLs.

Workaround: Download the files and deploy them from your local file system.

The third level of nested objects in a virtual machine folder is not visible

Perform the following steps:

1. Navigate to a data center and create a virtual machine folder.
2. In the virtual machine folder, create a nested virtual machine folder.
3. In the second folder, create another nested virtual machine, virtual machine folder, vApp, or VM Template.

As a result, from the VMs and Templates inventory tree you cannot see the objects in the third nested folder.

Workaround: To see the objects in the third nested folder, navigate to the second nested folder and select the VMs tab.

vSphere HA and Fault Tolerance Issues

VMs in a cluster might be orphaned after recovering from storage inaccessibility such as a cluster wide APD

Some VMs might be in orphaned state after cluster wide APD recovers, even if HA and VMCP are enabled on the cluster.

This issue might be encountered when the following conditions occur simultaneously:

- All hosts in the cluster experience APD and do not recover until VMCP timeout is reached.
- HA primary initiates failover due to APD on a host.
- Power on API during HA failover fails due to one of the following:
  - APD across the same host
  - Cascading APD across the entire cluster
  - Storage issues
  - Resource unavailability
- FDM unregistration and VCs steal VM logic might initiate during a window where FDM has not unregistered the failed VM and VC's host synchronization responds that multiple hosts are reporting the same VM. Both FDM and VC unregister the different registered copies of the same VM from different hosts, causing the VM to be orphaned.

Workaround: You must unregister and reregister the orphaned VMs manually within the cluster after the APD recovers.

If you do not manually reregister the orphaned VMs, HA attempts failover of the orphaned VMs, but it might take between 5 to 10 hours depending on when APD recovers.

The overall functionality of the cluster is not affected in these cases and HA will continue to protect the VMs. This is an anomaly in what gets displayed on VC for the duration of the problem.

vSphere Lifecycle Manager Issues

You cannot enable NSX-T on a cluster that is already enabled for managing image setup and updates on all hosts collectively

NSX-T is not compatible with the vSphere Lifecycle Manager functionality for image management. When you enable a cluster for image setup and updates on all hosts in the cluster collectively, you cannot enable NSX-T on that cluster. However, you can deploy NSX Edges to this cluster.

Workaround: Move the hosts to a new cluster that you can manage with baselines and enable NSX-T on that new cluster.

vSphere Lifecycle Manager and vSAN File Services cannot be simultaneously enabled on a vSAN cluster in vSphere 7.0 release

If vSphere Lifecycle Manager is enabled on a cluster, vSAN File Services cannot be enabled on the same cluster and vice versa. In order to enable vSphere Lifecycle Manager on a cluster, which has VSAN File Services enabled already, first disable vSAN File Services and retry the operation. Please note that if you transition to a cluster that is managed by a single image, vSphere Lifecycle Manager cannot be disabled on that cluster.

Workaround: None.

When a hardware support manager is unavailable, vSphere High Availability (HA) functionality is impacted

If hardware support manager is unavailable for a cluster that you manage with a single image, where a firmware and drivers addon is selected and vSphere HA is enabled, the vSphere HA functionality is impacted. You may experience the following errors.

- Configuring vSphere HA on a cluster fails.
- Cannot complete the configuration of the vSphere HA agent on a host: `Applying HA VIBs on the cluster encountered a failure.`
- Remediating vSphere HA fails: `A general system error occurred: Failed to get Effective Component map.`
- Disabling vSphere HA fails: Delete Solution task failed. `A general system error occurred: Cannot find hardware support package from depot or hardware support manager.`

Workaround:

- If the hardware support manager is temporarily unavailable, perform the following steps.

1. Reconnect the hardware support manager to vCenter Server.
2. Select a cluster from the Hosts and Cluster menu.
3. Select the Configure tab.
4. Under Services, click vSphere Availability.
5. Re-enable vSphere HA.

- If the hardware support manager is permanently unavailable, perform the following steps.

1. Remove the hardware support manager and the hardware support package from the image specification
2. Re-enable vSphere HA.
3. Select a cluster from the Hosts and Cluster menu.
4. Select the Updates tab.
5. Click Edit .
6. Remove the firmware and drivers addon and click Save.
7. Select the Configure tab.
8. Under Services, click vSphere Availability.
9. Re-enable vSphere HA.

I/OFilter is not removed from a cluster after a remediation process in vSphere Lifecycle Manager

Removing I/OFilter from a cluster by remediating the cluster in vSphere Lifecycle Manager, fails with the following error message: `iofilter XXX already exists` . The iofilter remains listed as installed.

Workaround:

1. Call IOFilter API `UninstallIoFilter_Task` from the vCenter Server managed object (IoFilterManager).
2. Remediate the cluster in vSphere Lifecycle Manager.
3. Call IOFilter API `ResolveInstallationErrorsOnCluster_Task` from the vCenter Server managed object (IoFilterManager) to update the database.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, adding hosts causes a vSphere HA error state

Adding one or multiple ESXi hosts during a remediation process of a vSphere HA enabled cluster, results in the following error message: `Applying HA VIBs on the cluster encountered a failure.`

Workaround: After the cluster remediation operation has finished, perform one of the following tasks.

- Right-click the failed ESXi host and select *Reconfigure for vSphere HA*.
- Disable and re-enable vSphere HA for the cluster.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, disabling and re-enabling vSphere HA causes a vSphere HA error state

Disabling and re-enabling vSphere HA during remediation process of a cluster, may fail the remediation process due to vSphere HA health checks reporting that hosts don't have vSphere HA VIBs installed. You may see the following error message: `Setting desired image spec for cluster failed.`

Workaround: After the cluster remediation operation has finished, disable and re-enable vSphere HA for the cluster.

Checking for recommended images in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the recommendation generation task could take more than an hour to finish or may appear to hang. The completion time for the recommendation task depends on the number of devices configured on each host and the number of image candidates from the depot that vSphere Lifecycle Manager needs to process before obtaining a valid image to recommend.

Workaround: None.

Checking for hardware compatibility in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the validation report generation task could take up to 30 minutes to finish or may appear to hang. The completion time depends on the number of devices configured on each host and the number of hosts configured in the cluster.

Workaround: None

Incomplete error messages in non-English languages are displayed, when remediating a cluster in vSphere Lifecycle Manager

You can encounter incomplete error messages for localized languages in the vCenter Server user interface. The messages are displayed, after a cluster remediation process in vSphere Lifecycle Manager fails. For example, your can observe the following error message.

The error message in English language: `Virtual machine 'VMC on DELL EMC -FileServer' that runs on cluster 'Cluster-1' reported an issue which prevents entering maintenance mode: Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

The error message in French language: `La VM « VMC on DELL EMC -FileServer », située sur le cluster « {Cluster-1} », a signalé un problème empêchant le passage en mode de maintenance : Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

Workaround: None.

Importing an image with no vendor addon, components, or firmware and drivers addon to a cluster which image contains such elements, does not remove the image elements of the existing image

Only the ESXi base image is replaced with the one from the imported image.

Workaround: After the import process finishes, edit the image, and if needed, remove the vendor addon, components, and firmware and drivers addon.

When you convert a cluster that uses baselines to a cluster that uses a single image, a warning is displayed that vSphere HA VIBs will be removed

Converting a vSphere HA enabled cluster that uses baselines to a cluster that uses a single image, may result a warning message displaying that `vmware-fdm` component will be removed.

Workaround: This message can be ignored. The conversion process installs the `vmware-fdm` component.

If vSphere Update Manager is configured to download patch updates from the Internet through a proxy server, after upgrade to vSphere 7.0 that converts Update Manager to vSphere Lifecycle Manager, downloading patches from VMware patch repository might fail

In earlier releases of vCenter Server you could configure independent proxy settings for vCenter Server and vSphere Update Manager. After an upgrade to vSphere 7.0, vSphere Update Manager service becomes part of the vSphere Lifecycle Manager service. For the vSphere Lifecycle Manager service, the proxy settings are configured from the vCenter Server appliance settings. If you had configured Update Manager to download patch updates from the Internet through a proxy server but the vCenter Server appliance had no proxy setting configuration, after a vCenter Server upgrade to version 7.0, the vSphere Lifecycle Manager fails to connect to the VMware depot and is unable to download patches or updates.

Workaround: Log in to the vCenter Server Appliance Management Interface, https://*vcenter-server-appliance-FQDN-or-IP-address*:5480, to configure proxy settings for the vCenter Server appliance and enable vSphere Lifecycle Manager to use proxy.

Miscellaneous Issues

When applying a host profile with version 6.5 to a ESXi host with version 7.0, the compliance check fails

Applying a host profile with version 6.5 to a ESXi host with version 7.0, results in Coredump file profile reported as not compliant with the host.

Workaround: There are two possible workarounds.

1. When you create a host profile with version 6.5, set an advanced configuration option VMkernel.Boot.autoCreateDumpFile to false on the ESXi host.
2. When you apply an existing host profile with version 6.5, add an advanced configuration option VMkernel.Boot.autoCreateDumpFile in the host profile, configure the option to a fixed policy, and set value to false.

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit minor throughput degradation when Dynamic Receive Side Scaling (DYN_RSS) or Generic RSS (GEN_RSS) feature is turned on

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit less than 5 percent throughput degradation when DYN_RSS and GEN_RSS feature is turned on, which is unlikely to impact normal workloads.

Workaround: You can disable DYN_RSS and GEN_RSS feature with the following commands:

```
# esxcli system module parameters set -m nmlx5_core -p "DYN_RSS=0 GEN_RSS=0"
# reboot
```

RDMA traffic between two VMs on the same host might fail in PVRDMA environment

In a vSphere 7.0 implementation of a PVRDMA environment, VMs pass traffic through the HCA for local communication if an HCA is present. However, loopback of RDMA traffic does not work on qedrntv driver. For instance, RDMA Queue Pairs running on VMs that are configured under same uplink port cannot communicate with each other.

In vSphere 6.7 and earlier, HCA was used for local RDMA traffic if SRQ was enabled. vSphere 7.0 uses HCA loopback with VMs using versions of PVRDMA that have SRQ enabled with a minimum of HW v14 using RoCE v2.

The current version of Marvell FastLinQ adapter firmware does not support loopback traffic between QPs of the same PF or port.

Workaround: Required support is being added in the out-of-box driver certified for vSphere 7.0. If you are using the inbox qedrntv driver, you must use a 3-host configuration and migrate VMs to the third host.

Unreliable Datagram traffic QP limitations in qedrntv driver

There are limitations with the Marvell FastLinQ qedrntv RoCE driver and Unreliable Datagram (UD) traffic. UD applications involving bulk traffic might fail with qedrntv driver. Additionally, UD QPs can only work with DMA Memory Regions (MR). Physical MRs or FRMR are not supported. Applications attempting to use physical MR or FRMR along with UD QP fail to pass traffic when used with qedrntv driver. Known examples of such test applications are `ibv_ud_pingpong` and `ib_send_bw`.

Standard RoCE and RoCEv2 use cases in a VMware ESXi environment such as iSER, NVMe-oF (RoCE) and PVRDMA are not impacted by this issue. Use cases for UD traffic are limited and this issue impacts a small set of applications requiring bulk UD traffic.

Marvell FastLinQ hardware does not support RDMA UD traffic offload. In order to meet the VMware PVRDMA requirement to support GSI QP, a restricted software only implementation of UD QP support was added to the qedrntv driver. The goal of the implementation is to provide support for control path GSI communication and is not a complete implementation of UD QP supporting bulk traffic and advanced features.

Since UD support is implemented in software, the implementation might not keep up with heavy traffic and packets might be dropped. This can result in failures with bulk UD traffic.

Workaround: Bulk UD QP traffic is not supported with qedrntv driver and there is no workaround at this time. VMware ESXi RDMA (RoCE) use cases like iSER, NVMe, RDMA and PVRDMA are unaffected by this issue.

Servers equipped with QLogic 578xx NIC might fail when frequently connecting or disconnecting iSCSI LUNs

If you trigger QLogic 578xx NIC iSCSI connection or disconnection frequently in a short time, the server might fail due to an issue with the qfle3 driver. This is caused by a known defect in the device's firmware.

Workaround: None.

ESXi might fail during driver unload or controller disconnect operation in Broadcom NVMe over FC environment

In Broadcom NVMe over FC environment, ESXi might fail during driver unload or controller disconnect operation and display an error message such as: `@BlueScreen: #PF Exception 14 in world 2098707:vmknvmeGener IP 0x4200225021cc addr 0x19`

Workaround: None.

ESXi does not display OEM firmware version number of i350/X550 NICs on some Dell servers

The inbox ixgben driver only recognizes firmware data version or signature for i350/X550 NICs. On some Dell servers the OEM firmware version number is programmed into the OEM package version region, and the inbox ixgben driver does not read this information. Only the 8-digit firmware signature is displayed.

Workaround: To display the OEM firmware version number, install async ixgben driver version 1.7.15 or later.

X710 or XL710 NICs might fail in ESXi

When you initiate certain destructive operations to X710 or XL710 NICs, such as resetting the NIC or manipulating VMKernel's internal device tree, the NIC hardware might read data from non-packet memory.

Workaround: Do not reset the NIC or manipulate vmkernel internal device state.

NVMe-oF does not guarantee persistent VMHBA name after system reboot

NVMe-oF is a new feature in vSphere 7.0. If your server has a USB storage installation that uses vmhba30+ and also has NVMe over RDMA configuration, the VMHBA name might change after a system reboot. This is because the VMHBA name assignment for NVMe over RDMA is different from PCIe devices. ESXi does not guarantee persistence.

Workaround: None.

Backup fails for vCenter database size of 300 GB or greater

If the vCenter database size is 300 GB or greater, the file-based backup will fail with a timeout. The following error message is displayed: `Timeout! Failed to complete in 72000 seconds`

Workaround: None.

A restore of vCenter Server 7.0 which is upgraded from vCenter Server 6.x with External Platform Services Controller to vCenter Server 7.0 might fail

When you restore a vCenter Server 7.0 which is upgraded from 6.x with External Platform Services Controller to vCenter Server 7.0, the restore might fail and display the following error: `Failed to retrieve appliance storage list`

Workaround: During the first stage of the restore process, increase the storage level of the vCenter Server 7.0. For example if the vCenter Server 6.7 External Platform Services Controller setup storage type is small, select storage type large for the restore process.

Enabled SSL protocols configuration parameter is not configured during a host profile remediation process

`Enabled SSL protocols` configuration parameter is not configured during a host profile remediation and only the system default protocol `tlsv1.2` is enabled. This behavior is observed for a host profile with version 7.0 and earlier in a vCenter Server 7.0 environment.

Workaround: To enable TLSV 1.0 or TLSV 1.1 SSL protocols for SFCB, log in to an ESXi host by using SSH, and run the following ESXCLI command: `esxcli system wbem -P <protocol_name>`

Unable to configure Lockdown Mode settings by using Host Profiles

Lockdown Mode cannot be configured by using a security host profile and cannot be applied to multiple ESXi hosts at once. You must manually configure each host.

Workaround: In vCenter Server 7.0, you can configure Lockdown Mode and manage Lockdown Mode exception user list by using a security host profile.

When a host profile is applied to a cluster, Enhanced vMotion Compatibility (EVC) settings are missing from the ESXi hosts

Some settings in the VMware config file `/etc/vmware/config` are not managed by Host Profiles and are blocked, when the config file is modified. As a result, when the host profile is applied to a cluster, the EVC settings are lost, which causes loss of EVC functionalities. For example, unmasked CPUs can be exposed to workloads.

Workaround: Reconfigure the relevant EVC baseline on cluster to recover the EVC settings.

Using a host profile that defines a core dump partition in vCenter Server 7.0 results in an error

In vCenter Server 7.0, configuring and managing a core dump partition in a host profile is not available. Attempting to apply a host profile that defines a core dump partition, results in the following error: `No valid coredump partition found.`

Workaround: None. In vCenter Server 7.0., Host Profiles supports only file-based core dumps.

If you run the ESXCLI command to unload the firewall module, the hostd service fails and ESXi hosts lose connectivity

If you automate the firewall configuration in an environment that includes multiple ESXi hosts, and run the ESXCLI command `esxcli network firewall unload` that destroys filters and unloads the firewall module, the hostd service fails and ESXi hosts lose connectivity.

Workaround: Unloading the firewall module is not recommended at any time. If you must unload the firewall module, use the following steps:

1. Stop the hostd service by using the command: `/etc/init.d/hostd stop.`
2. Unload the firewall module by using the command: `esxcli network firewall unload.`
3. Perform the required operations.
4. Load the firewall module by using the command: `esxcli network firewall load.`
5. Start the hostd service by using the command: `/etc/init.d/hostd start.`

vSphere Storage vMotion operations might fail in a vSAN environment due to an unauthenticated session of the Network File Copy (NFC) manager

Migrations to a vSAN datastore by using vSphere Storage vMotion of virtual machines that have at least one snapshot and more than one virtual disk with different storage policy might fail. The issue occurs due to an unauthenticated session of the NFC manager because the Simple Object Access Protocol (SOAP) body exceeds the allowed size.

Workaround: First migrate the VM home namespace and just one of the virtual disks. After the operation completes, perform a disk only migration of the remaining 2 disks.

Changes in the properties and attributes of the devices and storage on an ESXi host might not persist after a reboot

If the device discovery routine during a reboot of an ESXi host times out, the jumpstart plug-in might not receive all configuration changes of the devices and storage from all the registered devices on the host. As a result, the process might restore the properties of some devices or storage to the default values after the reboot.

Workaround: Manually restore the changes in the properties of the affected device or storage.

If you use a beta build of ESXi 7.0, ESXi hosts might fail with a purple diagnostic screen during some lifecycle operations

If you use a beta build of ESXi 7.0, ESXi hosts might fail with a purple diagnostic screen during some lifecycle operations such as unloading a driver or switching between ENS mode and native driver mode. For example, if you try to change the ENS mode, in the backtrace you see an error message similar to: `case ENS::INTERRUPT::NoVM_DeviceStateWithGracefulRemove hit BlueScreen: ASSERT bora/vmkernel/main/dlmalloc.c:2733` This issue is specific for beta builds and does not affect release builds such as ESXi 7.0.

Workaround: Update to ESXi 7.0 GA.

You cannot create snapshots of virtual machines due to an error that a digest operation has failed

A rare race condition when an All-Paths-Down (APD) state occurs during the update of the Content Based Read Cache (CBRC) digest file might cause inconsistencies in the digest file. As a result, you cannot create virtual machine snapshots. You see an error such as `An error occurred while saving the snapshot: A digest operation has failed` in the backtrace.

Workaround: Power cycle the virtual machines to trigger a recompute of the CBRC hashes and clear the inconsistencies in the digest file.

If you upgrade your ESXi hosts to version 7.0 Update 3, but your vCenter Server is of an earlier version, Trusted Platform Module (TPM) attestation of the ESXi hosts fails

If you upgrade your ESXi hosts to version 7.0 Update 3, but your vCenter Server is of an earlier version, and you enable TPM, ESXi hosts fail to pass attestation. In the vSphere Client, you see the warning Host TPM attestation alarm. The Elliptic Curve Digital Signature Algorithm (ECDSA) introduced with ESXi 7.0 Update 3 causes the issue when vCenter Server is not of version 7.0 Update 3.

Workaround: Upgrade your vCenter Server to 7.0 Update 3 or acknowledge the alarm.

You see warnings in the boot loader screen about TPM asset tags

If a TPM-enabled ESXi host has no asset tag set on, you might see idle warning messages in the boot loader screen such as:

```
Failed to determine TPM asset tag size: Buffer too smallFailed to measure asset tag into TPM: Buffer too small
```

Workaround: Ignore the warnings or set an asset tag by using the command `$ esxcli hardware tpm tag set -d`

The sensord daemon fails to report ESXi host hardware status

A logic error in the IPMI SDR validation might cause `sensord` to fail to identify a source for power supply information. As a result, when you run the command `vsish -e get /power/hostStats` , you might not see any output.

Workaround: None

If an ESXi host fails with a purple diagnostic screen, the netdump service might stop working

In rare cases, if an ESXi host fails with a purple diagnostic screen, the netdump service might fail with an error such as `NetDump FAILED: Couldn't attach to dump server at IP x.x.x.x.`

Workaround: Configure the VMkernel core dump to use local storage.

You see frequent VMware Fault Domain Manager (FDM) core dumps on multiple ESXi hosts

In some environments, the number of datastores might exceed the FDM file descriptor limit. As a result, you see frequent core dumps on multiple ESXi hosts indicating FDM failure.

Workaround: Increase the FDM file descriptor limit to 2048. You can use the setting `das.config.fdm.maxFds` from the vSphere HA advanced options in the vSphere Client. For more information, see Set Advanced Options.

Virtual machines on a vSAN cluster with enabled NSX-T and a converged vSphere Distributed Switch (CVDS) in a VLAN transport zone cannot power on after a power off

If a secondary site is 95% disk full and VMs are powered off before simulating a secondary site failure, during recovery some of the virtual machines fail to power on. As a result, virtual machines become unresponsive. The issue occurs regardless if site recovery includes adding disks or ESXi hosts or CPU capacity.

Workaround: Select the virtual machines that do not power on and change the network to VM Network from Edit Settings on the VM context menu.

ESXI hosts might fail with a purple diagnostic screen with an error Assert at bora/modules/vmkernel/vmfs/fs6Journal.c:835

In rare cases, for example when running SESparse tests, the number of locks per transaction in a VMFS datastore might exceed the limit of 50 for the `J6_MAX_TXN_LOCKACTIONS` parameter. As a result, ESXi hosts might fail with a purple diagnostic screen with an error `Assert at bora/modules/vmkernel/vmfs/fs6Journal.c:835` .

Workaround: None

If you modify the netq_rss_ens parameter of the nmlx5_core driver, ESXi hosts might fail with a purple diagnostic screen

If you try to enable the `netq_rss_ens` parameter when you configure an enhanced data path on the `nmlx5_core` driver, ESXi hosts might fail with a purple diagnostic screen. The `netq_rss_ens` parameter, which enables NetQ RSS, is disabled by default with a value of `0` .

Workaround: Keep the default value for the `netq_rss_ens` module parameter in the `nmlx5_core` driver.

ESXi might terminate I/O to NVMeOF devices due to errors on all active paths

Occasionally, all active paths to NVMeOF device register I/O errors due to link issues or controller state. If the status of one of the paths changes to Dead, the High Performance Plug-in (HPP) might not select another path if it shows high volume of errors. As a result, the I/O fails.

Workaround: Disable the configuration option **/Misc/HppManageDegradedPaths** to unblock the I/O.

Upgrade to ESXi 7.0 Update 3 might fail due to changed name of the inbox i40enu network driver

Starting with vSphere 7.0 Update 3, the inbox i40enu network driver for ESXi changes name back to i40en. The i40en driver was renamed to i40enu in vSphere 7.0 Update 2, but the name change impacted some upgrade paths. For example, rollup upgrade of ESXi hosts that you manage with baselines and baseline groups from 7.0 Update 2 or 7.0 Update 2a to 7.0 Update 3 fails. In most cases, the i40enu driver upgrades to ESXi 7.0 Update 3 without any additional steps. However, if the driver upgrade fails, you cannot update ESXi hosts that you manage with baselines and baseline groups. You also cannot use host seeding or a vSphere Lifecycle Manager single image to manage the ESXi hosts. If you have already made changes related to the i40enu driver and devices in your system, before upgrading to ESXi 7.0 Update 3, you must uninstall the i40enu VIB or Component on ESXi, or first upgrade ESXi to ESXi 7.0 Update 2c.

Workaround: For more information, see VMware knowledge base article 85982.

SSH access fails after you upgrade to ESXi 7.0 Update 3d

After you upgrade to ESXi 7.0 Update 3d, SSH access might fail in certain conditions due to an update of OpenSSH to version 8.8.

Workaround: For more information, see VMware knowledge base article 88055.

USB device passthrough from ESXi hosts to virtual machines might fail

A USB modem device might simultaneously claim multiple interfaces by the VMkernel and block the device passthrough to VMs.

Workaround: You must apply the USB.quirks advanced configuration on the ESXi host to ignore the NET interface from VMkernel and allow the USB modem to passthrough to VMs. You can apply the configuration in 3 alternative ways:

1. Access the ESXi shell and run the following command: `esxcli system settings advanced set -o /USB/quirks -s 0xvvvv:0xpppp:0:0xffff:UQ_NET_IGNORE | |- Device Product ID |------- Device Vendor ID`
   For example, for the Gemalto M2M GmbH Zoom 4625 Modem(`vid:pid/1e2d:005b`), you can have the command `esxcli system settings advanced set` **-o** `/USB/quirks -s 0x1e2d:0x005b:0:0xffff:UQ_NET_IGNORE`
   Reboot the ESXi host.
2. Set the advanced configuration from the vSphere Client or the vSphere Web Client and reboot the ESXi host.
3. Use a Host Profile to apply the advanced configuration.

For more information on the steps, see VMware knowledge base article 80416.

HTTP requests from certain libraries to vSphere might be rejected

The HTTP reverse proxy in vSphere 7.0 enforces stricter standard compliance than in previous releases. This might expose pre-existing problems in some third-party libraries used by applications for SOAP calls to vSphere.

If you develop vSphere applications that use such libraries or include applications that rely on such libraries in your vSphere stack, you might experience connection issues when these libraries send HTTP requests to VMOMI. For example, HTTP requests issued from vijava libraries can take the following form:

```
POST /sdk HTTP/1.1
SOAPAction
Content-Type: text/xml; charset=utf-8
User-Agent: Java/1.8.0_221
```

The syntax in this example violates an HTTP protocol header field requirement that mandates a colon after SOAPAction. Hence, the request is rejected in flight.

Workaround: Developers leveraging noncompliant libraries in their applications can consider using a library that follows HTTP standards instead. For example, developers who use the vijava library can consider using the latest version of the yavijava library instead.

You might see a dump file when using Broadcom driver lsi_msgpt3, lsi_msgpt35 and lsi_mr3

When using the lsi_msgpt3, lsi_msgpt35 and lsi_mr3 controllers, there is a potential risk to see dump file lsuv2-lsi-drivers-plugin-util-zdump. There is an issue when exiting the storelib used in this plugin utility. There is no impact on ESXi operations, you can ignore the dump file.

Workaround: You can safely ignore this message. You can remove the lsuv2-lsi-drivers-plugin with the following command:

```
esxcli software vib remove -n lsuv2-lsiv2-drivers-plugin
```

You might see reboot is not required after configuring SR-IOV of a PCI device in vCenter, but device configurations made by third party extensions might be lost and require reboot to be re-applied.

In ESXi 7.0, SR-IOV configuration is applied without a reboot and the device driver is reloaded. ESXi hosts might have third party extensions perform device configurations that need to run after the device driver is loaded during boot. A reboot is required for those third party extensions to re-apply the device configuration.

Workaround: You must reboot after configuring SR-IOV to apply third party device configurations.

vSphere Client Issues

BIOS manufacturer displays as "--" in the vSphere Client

In the vSphere Client, when you select an ESXi host and navigate to **Configure** > **Hardware** > **Firmware**, you see `--` instead of the BIOS manufacturer name.

Workaround: For more information, see VMware knowledge base article 88937.

vCenter Server Update and Patch Release Notes

VMware vCenter Server 7.0 Update 3u Release Notes

This document contains the following sections

- Introduction
- What's New
- Patches Contained in This Release
- Known Issues from Prior Releases

Introduction

VMware vCenter Server 7.0 Update 3u | 31 MAR 2025 | ISO Build 24614210 Check for additions and updates to these release notes.

What's New

- VMware vCenter Server 7.0 Update 3u serves as a vehicle for VMware vSphere with Tanzu and does not deliver vCenter Server fixes.

Patches Contained in This Release

Patch for VMware vCenter 7.0 Update 3u

Download Filename	VMware-vCenter-Server-Appliance-7.0.3.02300-24614210-patch-FP.iso
Build	24614210
Download Size	6701.3 MB
md5sum	3ca90d9abb05a79c1b76ff0c573b0228
sha256checksum	483ec3c8184281e69f720ff11d0ad896fc709b1785ec20409f12360f9a83a629
PRs fixed	3479424
CVEs	N/A

Download and Installation

Log in to the Broadcom Support Portal to download this patch.

For download instructions for earlier releases, see Download Broadcom products and software.

For more information on using the vCenter Server shells, see VMware knowledge base article 2100508.

For more information on patching vCenter Server, see Patching the vCenter Server Appliance.

For more information on staging patches, see Stage Patches to vCenter Server Appliance.

For more information on installing patches, see Install vCenter Server Appliance Patches.

For more information on patching using the Appliance Management Interface, see Patching the vCenter Server by Using the Appliance Management Interface.

Known Issues from Prior Releases

vSphere Cluster Services Issues

If all vSphere Cluster Service agent virtual machines in a cluster are down, vSphere DRS does not function in the cluster

If vSphere Cluster Service agent virtual machines fail to deploy or power on in a cluster, services such as vSphere DRS might be impacted.

Workaround: For more information on the issue and workarounds, see VMware knowledge base article 79892.

System virtual machines that support vSphere Cluster Services might impact cluster and datastore maintenance workflows

In vCenter Server 7.0 Update 1, vSphere Cluster Services adds a set of system virtual machines in every vSphere cluster to ensure the healthy operation of vSphere DRS. The system virtual machines deploy automatically with an implicit datastore selection logic. Depending on your cluster configuration, the system virtual machines might impact some of the cluster and datastore maintenance workflows.

Workaround: For more information on the impacted workflows and possible workarounds, see VMware knowledge base articles 79892 and 80483.

Installation, Upgrade, and Migration Issues

Upgrade to vSphere 7.0 Update 3c might require additional steps to force a full host-sync

The supported upgrade sequence for vSphere systems is first to upgrade vCenter Server and then ESXi. However, in certain environments with ESXi hosts of version 7.0 Update 2d and later, you need to update ESXi first to 7.0 Update 3c and then vCenter Server. Such an upgrade sequence requires additional steps to force a full host-sync.

Workaround: Log in to the appliance shell as a user with super administrative privileges (for example, `root`) and follow these steps:

1. Stop the vpxd service.
2. Run the command `/opt/vmware/vpostgres/current/bin/psql -U postgres -d VCDB -c "update VPX_HOST_SYNC_GEN set master_gen=0 where host_id in (select id from VPX_HOST where product_version like '7.0.3%')"`.
3. Start the vpxd service.

Patching vCenter to version 7.0 Update 3q might fail due to unsupported TLS ciphers in the Envoy proxy configuration

During the update of a vCenter instance to version 7.0 Update 3q, some services might fail to start due to custom configuration of the TLS cipher suites in the file `/etc/vmware-rhttpproxy/config.xml` . As a result, in the vSphere Client you see a warning such as `An error occurred while starting service 'vpxd-svcs'` and the process fails. If you use the Virtual Appliance Management Interface, you see an error such as `Installation Failed - Exception occurred in postInstallHook.`

Workaround: See KB 369485 for steps how to reset the TLS ciphers to their defaults and retry the vCenter update.

Hot-patched ESXi hosts with both i40en and i40enu Intel network drivers installed might fail to configure vSphere High Availability after upgrade to vCenter Server 7.0 Update 3c

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3c adds an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. However, if you apply an ESXi hot patch that is released after vCenter Server 7.0 Update 3c and then upgrade your system to vCenter Server 7.0 Update 3c, the hot patch might not be listed in the precheck. As a result, you might not follow the proper steps to the upgrade and vSphere HA might fail to configure on such hosts.

Workaround: Upgrade the hot-patched ESXi hosts to version 7.0 Update 3c.

The vCenter Upgrade/Migration pre-checks fail with "Unexpected error 87"

The vCenter Server Upgrade/Migration pre-checks fail when the Security Token Service (STS) certificate does not contain a Subject Alternative Name (SAN) field. This situation occurs when you have replaced the vCenter 5.5 Single Sign-On certificate with a custom certificate that has no SAN field, and you attempt to upgrade to vCenter Server 7.0. The upgrade considers the STS certificate invalid and the pre-checks prevent the upgrade process from continuing.

Workaround: Replace the STS certificate with a valid certificate that contains a SAN field then proceed with the vCenter Server 7.0 Upgrade/Migration.

Problems upgrading to vSphere 7.0 with pre-existing CIM providers

After upgrade, previously installed 32-bit CIM providers stop working because ESXi requires 64-bit CIM providers. Customers may lose management API functions related to CIMPDK, NDDK (native DDK), HEXDK, VAIODK (IO filters), and see errors related to **uwglibc** dependency.

The syslog reports module missing, "32 bit shared libraries not loaded."

Workaround: There is no workaround. The fix is to download new 64-bit CIM providers from your vendor.

Patching to vCenter Server 7.0 Update 1 from earlier versions of vCenter Server 7.x is blocked when vCenter Server High Availability is enabled

Patching to vCenter Server 7.0 Update 1 from earlier versions of vCenter Server 7.x is blocked when vCenter Server High Availability is active.

Workaround: To patch your system to vCenter Server 7.0 Update 1 from earlier versions of vCenter Server 7.x, you must remove vCenter Server High Availability and delete the passive and witness nodes. After the upgrade, you must re-create your vCenter Server High Availability clusters.

Migration of a 6.7.x vCenter Server system to vCenter Server 7.x fails with an UnicodeEncodeError

If you select the option to import all data for configuration, inventory, tasks, events, and performance metrics, the migration of a 6.7.x vCenter Server system to vCenter Server 7.x might fail for any vCenter Server system that uses a non-English locale. At step 1 of stage 2 of the migration, in the vSphere Client, you see an error such as:

```
Error while exporting events and tasks data: …ERROR UnicodeEncodeError: Traceback (most recent call last):
```

Workaround: You can complete the migration operation by doing either:

- Select the default option **Configuration and Inventory** at the end of stage 1 of the migration. This option does not include tasks and events data.
- Clean the data in the events tables and run the migration again.

If a Windows vCenter Server system has a database password containing non-ASCII characters, pre-checks of the VMware Migration Assistant fail

If you try to migrate a 6.x vCenter Server system to vCenter Server 7.x by using the VMware Migration Assistant, and your system has a Windows OS, and uses an external database with a password containing non-ASCII characters, the operation fails. For example, Admin!23迁移. In the Migration Assistant console, you see the following error:

```
Error:Component com.vmware.vcdb failed with internal errorResolution:File Bugzilla PR to VPX/VPX/vcdb-upgrade
```

Workaround: None

During an update from vCenter Server 7.x to vCenter Server 7.0 Update 1, you get prompts to provide the vCenter Single Sign-On password

During an update from vCenter Server 7.x to vCenter Server 7.0 Update 1, you get prompts to provide vCenter Single Sign-On administrator password.

Workaround: If you run the update by using the vCenter Server Management Interface, you must provide the vCenter Single Sign-On administrator password.

If you run the update by using software-packages or CLI in an interactive manner, you must interactively provide the vCenter Single Sign-On administrator password.

If you run the update by using software-packages or CLI in a non-interactive manner, you must provide the vCenter Single Sign-On administrator password by an answer file in the format

```
{ "vmdir.password": "SSO Password of Administrator@<SSO-DOMAIN> user" }
```

Smart Card and RSA SecurID authentication might stop working after upgrading to vCenter Server 7.0

If you have configured vCenter Server for either Smart Card or RSA SecurID authentication, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057 before starting the vSphere 7.0 upgrade process. If you do not perform the workaround as described in the KB, you might see the following error messages and Smart Card or RSA SecurID authentication does not work.

"Smart card authentication may stop working. Smart card settings may not be preserved, and smart card authentication may stop working."

or

"RSA SecurID authentication may stop working. RSA SecurID settings may not be preserved, and RSA SecurID authentication may stop working."

Workaround: Before upgrading to vSphere 7.0, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057.

You might not be able to apply or remove NSX while you add ESXi hosts by using a vSphere Lifecycle Manager image to a cluster with enabled VMware vSphere High Availability

If you start an operation to apply or remove NSX while adding multiple ESXi hosts by using a vSphere Lifecycle Manager image to a vSphere HA-enabled cluster, the NSX-related operations might fail with an error in the vSphere Client such as:

```
vSphere HA agent on some of the hosts on cluster <cluster_name> is neither vSphere HA master agent nor connected to vSphere HA master agent. Verify that the HA configuration is correct.
```

The issue occurs because vSphere Lifecycle Manager configures vSphere HA for the ESXi hosts being added to the cluster one at a time. If you run an operation to apply or remove NSX while vSphere HA configure operations are still in progress, NSX operations might queue up between the vSphere HA configure operations for two different ESXi hosts. In such a case, the NSX operation fails with a cluster health check error, because the state of the cluster at that point does not match the expected state that all ESXi hosts have vSphere HA configured and running. The more ESXi hosts you add to a cluster at the same time, the more likely the issue is to occur.

Workaround: Deactivate and enable Sphere HA on the cluster. Proceed with the operations to apply or remove NSX.

After an upgrade of a vCenter Server 7.0 system, you cannot see the IP addresses of pods in the vSphere Pod Summary tab of the vSphere Client

If you upgrade your vCenter Server 7.0 system to a later version, you can no longer see the IP addresses of pods in the **vSphere Pod Summary** tab of the vSphere Client.

Workaround: Use the Kubernetes CLI Tools for vSphere to review details of pods:

1. As a prerequisite, copy the pod and namespace names.
   - In the vSphere Client, navigate to **Workload Management** > **Clusters.**
   - Copy the IP displayed in the **Control Plane Node IP Address** tab.
   - You can navigate to `https://<control_plane_node_IP_address>` and download the Kubernetes CLI Tools, `kubectl` and `kubectl-vsphere`.
     Alternatively, follow the steps in Download and Install the Kubernetes CLI Tools for vSphere.
2. Use the CLI plug-in for vSphere to review the pod details.
   a. Log in to the Supervisor cluster by using the command
      ```
      kubectl vsphere login --server=https://<server_adress> --vsphere-username <your user account name> --insecure-skip-tls-verify
      ```
   b. By using the names copied in step 1, run the commands for retrieving the pod details:
      ```
      kubectl config use-context <namespace_name>
      ```
      and
      ```
      kubectl describe pod <pod_name> -n <namespace_name>
      ```

As a result, you can see the IP address in an output similar to:

```
$ kubectl describe pod helloworld -n my-podvm-ns ...

Status: Running

IP: 10.0.0.10
```

```
IPs:
IP: 10.0.0.10 ...
```

Upgrading a vCenter Server with an external Platform Services Controller from 6.7u3 to 7.0 fails with VMAFD error

When you upgrade a vCenter Server deployment using an external Platform Services Controller, you converge the Platform Services Controller into a vCenter Server appliance. If the upgrade fails with the error `install.vmafd.vmdir_vdcpromo_error_21` , the VMAFD firstboot process has failed. The VMAFD firstboot process copies the VMware Directory Service Database (data.mdb) from the source Platform Services Controller and replication partner vCenter Server appliance.

Workaround: Deactivate TCP Segmentation Offload (TSO) and Generic Segmentation Offload (GSO) on the Ethernet adapter of the source Platform Services Controller or replication partner vCenter Server appliance before upgrading a vCenter Server with an external Platform Services Controller. See Knowledge Base article: https://kb.vmware.com/s/article/74678

vCenter Server system upgrades fail in the pre-check stage

Upgrades of your vCenter Server system might fail in the pre-check stage due to a limit in the authorization (Authz) connections. In the `/var/log/vmware/vpxd-svcs/vpxd-svcs*.log` file you see entries such as:

`Session count for user [after add]: <DOMAIN-NAME>\machine-xxxx is 200Session limit reached for user: <DOMAIN-NAME>\machine-xxxx with 200 sessions.`

You might also see delayed response from the vSphere Client to load the inventory.

Workaround: Restart vmware-vpxd-svcs in your vCenter Server system by using the command `service-control --restart vmware-vpxd-svcs` . Use the command only when no other activity runs in the vCenter Server system to avoid any interruptions to the workflow. For more information, see VMware knowledge base article 81953.

Upgrading vCenter Server using the CLI incorrectly preserves the Transport Security Layer (TLS) configuration for the vSphere Authentication Proxy service

If the vSphere Authentication Proxy service (`vmcam`) is configured to use a particular TLS protocol other than the default TLS 1.2 protocol, this configuration is preserved during the CLI upgrade process. By default, vSphere supports the TLS 1.2 encryption protocol. If you must use the TLS 1.0 and TLS 1.1 protocols to support products or services that do not support TLS 1.2, use the TLS Configurator Utility to enable or deactivate different TLS protocol versions.

Workaround: Use the TLS Configurator Utility to configure the `vmcam` port. To learn how to manage TLS protocol configuration and use the TLS Configurator Utility, see the *VMware Security* documentation.

You do not see a precheck error when patching to vCenter Server 7.0 Update 3c by using CLI

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3c adds an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. In some cases, if such hosts exist in your system, patching from an vCenter Server version earlier than 7.0 Update 3 to a version later than 7.0 Update 3 by using CLI might fail with the error `Installation failed. Retry to resume from the current state. Or please collect the VC support bundle..`

However, instead of this error, you must see the precheck error message.

Workaround: If you do not see the precheck error and patching your system to vCenter Server 7.0 Update 3c fails, make sure all ESXi hosts are upgraded to ESXi 7.0 Update 3c or higher, by using either a baseline created from an ISO or a single image, before upgrading vCenter Server. Do not use patch baselines based on the rollup bulletin. You can find additional debug log information at `/var/log/vmware/applmgmt` . For more details, see VMware knowledge base articles 87319 and 86447.

Smart card and RSA SecurID settings may not be preserved during vCenter Server upgrade

Authentication using RSA SecurID will not work after upgrading to vCenter Server 7.0. An error message will alert you to this issue when attempting to login using your RSA SecurID login.

Workaround: Reconfigure the smart card or RSA SecureID.

Upgrade to vSphere 7.0 Update 3c might require additional steps to force a full host-sync

The supported upgrade sequence for vSphere systems is first to upgrade vCenter Server and then ESXi. However, in certain environments with ESXi hosts of version 7.0 Update 2c and later, you need to update ESXi first to 7.0 Update 3c and then vCenter Server. Such an upgrade sequence requires additional steps to force a full host-sync.

Workaround: Log in to the appliance shell as a user with super administrative privileges (for example, `root`) and follow these steps:

1. Stop the vpxd service.
2. Run the command `/opt/vmware/vpostgres/current/bin/psql -U postgres -d VCDB -c "update VPX_HOST_SYNC_GEN set master_gen=0 where host_id in (select id from VPX_HOST where product_version like '7.0.3%')"`.
3. Start the vpxd service.

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with network error message

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with the error message `IP already exists in the network`. This prevents the migration process from configuring the network parameters on the new vCenter Server appliance. For more information, examine the log file: `/var/log/vmware/upgrade/UpgradeRunner.log`

Workaround:

1. Verify that all Windows Updates have been completed on the source vCenter Server for Windows instance, or deactivate automatic Windows Updates until after the migration finishes.
2. Retry the migration of vCenter Server for Windows to vCenter Server appliance 7.0.

Hot-patched ESXi hosts with both i40en and i40enu Intel network drivers installed might fail to configure vSphere High Availability after upgrade to vCenter Server 7.0 Update 3c

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3c adds an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. However, if you apply an ESXi hot patch that is released after vCenter Server 7.0 Update 3c and then upgrade your system to vCenter Server 7.0 Update 3c, the hot patch might not be listed in the precheck. As a result, you might not follow the proper steps to the upgrade and vSphere HA might fail to configure on such hosts.

Workaround: Upgrade the hot-patched ESXi hosts to version 7.0 Update 3c.

When you configure the number of virtual functions for an SR-IOV device by using the max_vfs module parameter, the changes might not take effect

In vSphere 7.0, you can configure the number of virtual functions for an SR-IOV device by using the Virtual Infrastructure Management (VIM) API, for example, through the vSphere Client. The task does not require reboot of the ESXi host. After you use the VIM API configuration, if you try to configure the number of SR-IOV virtual functions by using the `max_vfs` module parameter, the changes might not take effect because they are overridden by the VIM API configuration.

Workaround: None. To configure the number of virtual functions for an SR-IOV device, use the same method every time. Use the VIM API or use the `max_vfs` module parameter and reboot the ESXi host.

Upgraded vCenter Server appliance instance does not retain all the secondary networks (NICs) from the source instance

During a major upgrade, if the source instance of the vCenter Server appliance is configured with multiple secondary networks other than the VCHA NIC, the target vCenter Server instance will not retain secondary networks other than the VCHA NIC. If the source instance is configured with multiple NICs that are part of VDS port groups, the NIC configuration will not be preserved during the upgrade. Configurations for vCenter Server appliance instances that are part of the standard port group will be preserved.

Workaround: None. Manually configure the secondary network in the target vCenter Server appliance instance.

After upgrading or migrating a vCenter Server with an external Platform Services Controller, users authenticating using Active Directory lose access to the newly upgraded vCenter Server instance

After upgrading or migrating a vCenter Server with an external Platform Services Controller, if the newly upgraded vCenter Server is not joined to an Active Directory domain, users authenticating using Active Directory will lose access to the vCenter Server instance.

Workaround: Verify that the new vCenter Server instance has been joined to an Active Directory domain. See Knowledge Base article: https://kb.vmware.com/s/article/2118543

Migrating a vCenter Server for Windows with an external Platform Services Controller using an Oracle database fails

If there are non-ASCII strings in the Oracle events and tasks table the migration can fail when exporting events and tasks data. The following error message is provided: UnicodeDecodeError

Workaround: None.

After an ESXi host upgrade, a Host Profile compliance check shows non-compliant status while host remediation tasks fail

The non-compliant status indicates an inconsistency between the profile and the host.

This inconsistency might occur because ESXi 7.0 does not allow duplicate claim rules, but the profile you use contains duplicate rules. For example, if you attempt to use the Host Profile that you extracted from the host before upgrading ESXi 6.5 or ESXi 6.7 to version 7.0 and the Host Profile contains any duplicate claim rules of system default rules, you might experience the problems.

Workaround:

1. Remove any duplicate claim rules of the system default rules from the Host Profile document.
2. Check the compliance status.
3. Remediate the host.
4. If the previous steps do not help, reboot the host.

Error message displays in the vCenter Server Management Interface

After installing or upgrading to vCenter Server 7.0, when you navigate to the Update panel within the vCenter Server Management Interface, the error message "Check the URL and try again" displays. The error message does not prevent you from using the functions within the Update panel, and you can view, stage, and install any available updates.

Workaround: None.

Patching witness or passive nodes of environments with VMware vCenter Server High Availability enabled might fail

In environments with vCenter Server High Availability enabled, patching a witness or passive node might fail with a message similar to:

`RuntimeError: unidentifiable C++ exception.`

Workaround: Deactivate vCenter Server High Availability. Apply patches to your vCenter Server system. Re-enable vCenter Server High Availability.

After patching your vCenter Server system to vCenter Server 7.0.0a, the TLS version of the VC Storage Clients might revert to the default

If you have a TLS configuration for the VC Storage Clients service different from the default TLS 1.2 only, the TLS version might revert to the default after patching your vCenter Server system to vCenter Server 7.0.0a.

Workaround: Use the TLS Configuration utility to enable or deactivate TLS versions on your vCenter Server system after the update.

After updating your system to vCenter Server 7.0.0b, you see systemd core dump in the /var/core folder

After updating your system to vCenter Server 7.0.0b from either vCenter Server 7.0.0a or vCenter Server 7.0, in the `/var/core` folder you see systemd core dump, such as `core.systemd-journal.393` and `core.systemd-udevd.405`. The core dump is harmless and can be removed.

Workaround: None

After updating your vCenter Server system to 7.0.0b, the vCenter Server version is not updated in the Direct Console User Interface (DCUI)

After updating your system to vCenter Server 7.0.0b from vCenter Server 7.0.0a or vCenter Server 7.0, you still see the previous vCenter Server version in the DCUI.

Workaround: After you complete the update, to refresh the vCenter Server version, in the appliance shell, run the command `/usr/lib/applmgmt/dcui/notify`.

Update Planner fails with error Configured repository is not accessible due to network connectivity or incorrect URL

If you use Update Planner, which is part of vSphere Lifecycle Manager used to facilitate vCenter Server updates, you might see the following error in the vSphere Client:

`Configured repository is not accessible due to network connectivity or incorrect URL. Verify the repository settings.`

The issue occurs when you use a custom local repository, such as `https:///uploads/dpe/` or a DBC path, to store the extracted . If the custom repository for URL-based patching has an authentication policy, Update Planner might not be able to fetch the list of available updates.

Workaround: Configure the custom repository such that authentication is not needed to access the custom repository URL.

After upgrading to vCenter Server 7.0.0b, you see vSphere HA errors on vSphere Lifecycle Manager Image based clusters

After upgrading to vCenter Server 7.0.0b, on vSphere Lifecycle Manager Image based clusters that are configured with vSphere HA, you might see error messages about the vSphere HA configuration after logging in for the first time to the environment. In the vSphere Client, you see messages such as:

`Cannot complete the configuration of the vSphere HA agent on the host.` or

`Applying HA VIBs on the cluster encountered a failure.`

The issue occurs because exports of the image depot might take long and cause a timeout of the task. In the `/storage/log/vmware/vmware-updatemgr/vum-server/vmware-vum-server.log` you see this message: `Export taking too long (Failure case)`

Workaround: This is a transient issue that resolves in 10 minutes after the vCenter Server is up and running. The issue does not affect any functionality. vSphere HA on the affected clusters operates as expected. All operations related to virtual machines, such as power on and migration, work across the vSphere HA-enabled clusters while this error recovery is still in progress.

You do not see a precheck error when patching to vCenter Server 7.0 Update 3d by using CLI

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3d and later add an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. In some cases, if such hosts exist in your system, patching from a vCenter Server version earlier than 7.0 Update 3 to a version later than 7.0 Update 3 by using CLI might fail with the error `Installation failed. Retry to resume from the current state. Or please collect the VC support bundle.` . However, instead of this error, you must see the precheck error message.

Workaround: If you do not see the precheck error and patching your system to vCenter Server 7.0 Update 3d fails, make sure all ESXi hosts are upgraded to ESXi 7.0 Update 3d, by using either a baseline created from an ISO or a single image, before upgrading vCenter Server. Do not use patch baselines based on the rollup bulletin. You can find additional debug log information at `/var/log/vmware/applmgmt` . For more details, see VMware knowledge base articles 87319 and 86447.

Security Features Issues

Encrypted virtual machine fails to power on when HA-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled HA on the Trusted Cluster and one or more hosts in the cluster fails attestation, an encrypted virtual machine cannot power on.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Encrypted virtual machine fails to power on when DRS-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled DRS on the Trusted Cluster and one or more hosts in the cluster fails attestation, DRS might try to power on an encrypted virtual machine on an unattested host in the cluster. This operation puts the virtual machine in a locked state.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Migrating or cloning encrypted virtual machines across vCenter Server instances fails when attempting to do so using the vSphere Client

If you try to migrate or clone an encrypted virtual machine across vCenter Server instances using the vSphere Client, the operation fails with the following error message: "The operation is not allowed in the current state."

Workaround: You must use the vSphere APIs to migrate or clone encrypted virtual machines across vCenter Server instances.

Networking Issues

PR3304411: After batch cloning and customizing Windows virtual machines, the VMs network might not be configured

When cloning Windows VMs in bulk, a MAC address conflict might occur, causing vCenter to reassign new MAC addresses to the VMs. As a result, the guest customization process fails to configure properly the VMs network because it cannot match the original MAC address to the corresponding network card.

This issue is resolved in this release.

When you use the VMware Remote Console, the envoy service might intermittently fail

An issue with the envoy service specific to the VMware Remote Console might lead to intermittent failures of the service. As a result, the vCenter Server Management Interface or vCenter Server APIs might also become unavailable.

Workaround: Use the vSphere Client as an alternative to the VMware Remote Console.

Reduced throughput in networking performance on Intel 82599/X540/X550 NICs

The new queue-pair feature added to ixgben driver to improve networking performance on Intel 82599EB/X540/X550 series NICs might reduce throughput under some workloads in vSphere 7.0 as compared to vSphere 6.7.

Workaround: To achieve the same networking performance as vSphere 6.7, you can deactivate the queue-pair with a module parameter. To deactivate the queue-pair, run the command:

```
# esxcli system module parameters set -p "QPair=0,0,0,0..." -m ixgben
```

After running the command, reboot.

If you try to deactivate vSphere with Tanzu on a vSphere cluster, the operation stops with an error

If some virtual machines outside of a Supervisor Cluster reside on any of the NSX segment port groups on the cluster, the cleanup script cannot delete such ports and deactivate vSphere with Tanzu on the cluster. In the vSphere Client, you see the error `Cleanup requests to NSX Manager failed` and the operation stops at `Removing` status. In the `/var/log/vmware/wcp/wcpsvc.log` file, you see an error message such as

```
Segment path=[...] has x VMs or VIFs attached. Disconnect all VMs and VIFs before deleting a segment.
```

Workaround: Delete the virtual machines indicated in the `/var/log/vmware/wcp/wcpsvc.log` file from the segment. Wait for the operation to restore.

After upgrading to NSX 6.4.7, when a static IPv6 address is assigned to workload VMs on an IPv6 network, the VMs are unable to ping the IPv6 gateway interface of the edge

This issue occurs after upgrading the vSphere Distributed Switches from 6.x to 7.0.

Workaround 1:

Select the VDS where all the hosts are connected, go to the **Edit** setting, and under **Multicast** option switch to basic.

Workaround 2:

Add the following rules on the edge firewall:

Ping allow rule.

Multicast Listener Discover (MLD) allow rule, which are icmp6, type 130 (v1) and type 143 (v2).

High throughput virtual machines may experience degradation in network performance when Network I/O Control (NetIOC) is enabled

Virtual machines requiring high network throughput can experience throughput degradation when upgrading from vSphere 6.7 to vSphere 7.0 with NetIOC enabled.

Workaround: Adjust the `ethernetx.ctxPerDev` setting to enable multiple worlds.

IPv6 traffic fails to pass through VMkernel ports using IPsec

When you migrate VMkernel ports from one port group to another, IPv6 traffic does not pass through VMkernel ports using IPsec.

Workaround: Remove the IPsec security association (SA) from the affected server, and then reapply the SA. To learn how to set and remove an IPsec SA, see the *vSphere Security* documentation.

Higher ESX network performance with a portion of CPU usage increase

ESX network performance may increase with a portion of CPU usage.

Workaround: Remove and add the network interface with only 1 rx dispatch queue. For example:

```
esxcli network ip interface remove --interface-name=vmk1
esxcli network ip interface add --interface-name=vmk1 --num-rxqueue=1
```

VM might lose Ethernet traffic after hot-add, hot-remove or storage vMotion

A VM might stop receiving Ethernet traffic after a hot-add, hot-remove or storage vMotion. This issue affects VMs where the uplink of the VNIC has SR-IOV enabled. PVRDMA virtual NIC exhibits this issue when the uplink of the virtual network is a Mellanox RDMA capable NIC and RDMA namespaces are configured.

Workaround: You can hot-remove and hot-add the affected Ethernet NICs of the VM to restore traffic. On Linux guest operating systems, restarting the network might also resolve the issue. If these workarounds have no effect, you can reboot the VM to restore network connectivity.

Change of IP address for a VCSA deployed with static IP address requires that you create the DNS records in advance

With the introduction of the DDNS, the DNS record update only works for VCSA deployed with DHCP configured networking. While changing the IP address of the vCenter server via VAMI, the following error is displayed:

The specified IP address does not resolve to the specified hostname.

Workaround: There are two possible workarounds.

1. Create an additional DNS entry with the same FQDN and desired IP address. Log in to the VAMI and follow the steps to change the IP address.
2. Log in to the VCSA using ssh. Execute the following script:
   `./opt/vmware/share/vami/vami_config_net`
   Use option 6 to change the IP adddress of eth0. Once changed, execute the following script:
   `./opt/likewise/bin/lw-update-dns`
   Restart all the services on the VCSA to update the IP information on the DNS server.

It may take several seconds for the NSX Distributed Virtual Port Group (NSX DVPG) to be removed after deleting the corresponding logical switch in NSX Manager.

As the number of logical switches increases, it may take more time for the NSX DVPG in vCenter Server to be removed after deleting the corresponding logical switch in NSX Manager. In an environment with 12000 logical switches, it takes approximately 10 seconds for an NSX DVPG to be deleted from vCenter Server.

Workaround: None.

Hostd runs out of memory and fails if a large number of NSX Distributed Virtual port groups are created.

In vSphere 7.0, NSX Distributed Virtual port groups consume significantly larger amounts of memory than opaque networks. For this reason, NSX Distributed Virtual port groups can not support the same scale as an opaque network given the same amount of memory.

Workaround:To support the use of NSX Distributed Virtual port groups, increase the amount of memory in your ESXi hosts. If you verify that your system has adequate memory to support your VMs, you can directly increase the memory of `hostd` using the following command.

```
localcli --plugin-dir /usr/lib/vmware/esxcli/int/ sched group setmemconfig --group-path
host/vim/vmvisor/hostd --units mb --min 2048 --max 2048
```

Note that this will cause `hostd` to use memory normally reserved for your environment's VMs. This may have the affect of reducing the number of VMs your ESXi host can support.

DRS may incorrectly launch vMotion if the network reservation is configured on a VM

If the network reservation is configured on a VM, it is expected that DRS only migrates the VM to a host that meets the specified requirements. In a cluster with NSX transport nodes, if some of the transport nodes join the transport zone by NSX-T Virtual Distributed Switch (N-VDS), and others by vSphere Distributed Switch (VDS) 7.0, DRS may incorrectly launch vMotion. You might encounter this issue when:

- The VM connects to an NSX logical switch configured with a network reservation.
- Some transport nodes join transport zone using N-VDS, and others by VDS 7.0, or, transport nodes join the transport zone through different VDS 7.0 instances.

Workaround: Make all transport nodes join the transport zone by N-VDS or the same VDS 7.0 instance.

When adding a VMkernel NIC (vmknic) to an NSX portgroup, vCenter Server reports the error "Connecting VMKernel adapter to a NSX Portgroup on a Stateless host is not a supported operation. Please use Distributed Port Group instead."

- For stateless ESXi on Distributed Virtual Switch (VDS), the vmknic on a NSX port group is blocked. You must instead use a Distributed Port Group.
- For stateful ESXi on VDS, vmknic on NSX port group is supported, but vSAN may have an issue if it is using vmknic on a NSX port group.

Workaround: Use a Distributed Port Group on the same VDS.

Enabling SRIOV from vCenter for QLogic 4x10GE QL41164HFCU CNA might fail

If you navigate to the **Edit Settings** dialog for physical network adapters and attempt to enable SR-IOV, the operation might fail when using QLogic 4x10GE QL41164HFCU CNA. Attempting to enable SR-IOV might lead to a network outage of the ESXi host.

Workaround: Use the following command on the ESXi host to enable SRIOV:

```
esxcfg-module
```

Storage Issues

VMFS datastores are not mounted automatically after disk hot remove and hot insert on HPE Gen10 servers with SmartPQI controllers

When SATA disks on HPE Gen10 servers with SmartPQI controllers without expanders are hot removed and hot inserted back to a different disk bay of the same machine, or when multiple disks are hot removed and hot inserted back in a different order, sometimes a new local name is assigned to the disk. The VMFS datastore on that disk appears as a snapshot and will not be mounted back automatically because the device name has changed.

Workaround: None. SmartPQI controller does not support unordered hot remove and hot insert operations.

ESXi might terminate I/O to NVMeOF devices due to errors on all active paths

Occasionally, all active paths to NVMeOF device register I/O errors due to link issues or controller state. If the status of one of the paths changes to Dead, the High Performance Plug-in (HPP) might not select another path if it shows high volume of errors. As a result, the I/O fails.

Workaround: Deactivate the configuration option **/Misc/HppManageDegradedPaths** to unblock the I/O.

VOMA check on NVMe based VMFS datastores fails with error

VOMA check is not supported for NVMe based VMFS datastores and will fail with the error:

```
ERROR: Failed to reserve device. Function not implemented
```

Example:

```
# voma -m vmfs -f check -d /vmfs/devices/disks/: <partition#>
Running VMFS Checker version 2.1 in check mode
Initializing LVM metadata, Basic Checks will be done

Checking for filesystem activity
Performing filesystem liveness check..|Scanning for VMFS-6 host activity (4096 bytes/HB, 1024 HBs).
ERROR: Failed to reserve device. Function not implemented
Aborting VMFS volume check
VOMA failed to check device : General Error
```

Workaround: None. If you need to analyse VMFS metadata, collect it using the `-l` option, and pass to VMware customer support. The command for collecting the dump is:

```
voma -l -f dump -d /vmfs/devices/disks/:<partition#>
```

Using the VM reconfigure API to attach an encrypted First Class Disk to an encrypted virtual machine might fail with error

If an FCD and a VM are encrypted with different crypto keys, your attempts to attach the encrypted FCD to the encrypted VM using the `VM reconfigure API` might fail with the error message:

```
Cannot decrypt disk because key or password is incorrect.
```

Workaround: Use the `attachDisk API` rather than the `VM reconfigure API` to attach an encrypted FCD to an encrypted VM.

ESXi host might get in non responding state if a non-head extent of its spanned VMFS datastore enters the Permanent Device Loss (PDL) state

This problem does not occur when a non-head extent of the spanned VMFS datastore fails along with the head extent. In this case, the entire datastore becomes inaccessible and no longer allows I/Os.

In contrast, when only a non-head extent fails, but the head extent remains accessible, the datastore heartbeat appears to be normal. And the I/Os between the host and the datastore continue. However, any I/Os that depend on the failed non-head extent start failing as well. Other I/O transactions might accumulate while waiting for the failing I/Os to resolve, and cause the host to enter the non responding state.

Workaround: Fix the PDL condition of the non-head extent to resolve this issue.

After recovering from APD or PDL conditions, VMFS datastore with enabled support for clustered virtual disks might remain inaccessible

You can encounter this problem only on datastores where the clustered virtual disk support is enabled. When the datastore recovers from an All Paths Down (APD) or Permanent Device Loss (PDL) condition, it remains inaccessible. The VMkernel log might show multiple `SCSI3 reservation conflict` messages similar to the following:

```
2020-02-18T07:41:10.273Z cpu22:1001391219)ScsiDeviceIO: vm 1001391219:
SCSIDeviceCmdCompleteCB:2972: Reservation conflict retries 544 for command 0x45ba814b8340
(op: 0x89) to device "naa.624a9370b97601e346f64ba900024d53"
```

The problem can occur because the ESXi host participating in the cluster loses SCSI reservations for the datastore and cannot always reacquire them automatically after the datastore recovers.

Workaround: Manually register the reservation using the following command:

```
vmkfstools -L registerkey /vmfs/devices/disks/<device name>
```

where the `<device name>` is the name of the device on which the datastore is created.

Virtual NVMe Controller is the default disk controller for Windows 10 guest operating systems

The Virtual NVMe Controller is the default disk controller for the following guest operating systems when using Hardware Version 15 or later:

Windows 10

Windows Server 2016

Windows Server 2019

Some features might not be available when using a Virtual NVMe Controller. For more information, see https://kb.vmware.com/s/article/2147714

Note: Some clients use the previous default of LSI Logic SAS. This includes ESXi host client and PowerCLI.

Workaround: If you need features not available on Virtual NVMe, switch to VMware Paravirtual SCSI (PVSCSI) or LSI Logic SAS. For information on using VMware Paravirtual SCSI (PVSCSI), see https://kb.vmware.com/s/article/1010398

After an ESXi host upgrade to vSphere 7.0, presence of duplicate core claim rules might cause unexpected behavior

Claim rules determine which multipathing plugin, such as NMP, HPP, and so on, owns paths to a particular storage device. ESXi 7.0 does not support duplicate claim rules. However, the ESXi 7.0 host does not alert you if you add duplicate rules to the existing claim rules inherited through an upgrade from a legacy release. As a result of using duplicate rules, storage devices might be claimed by unintended plugins, which can cause unexpected outcome.

Workaround: Do not use duplicate core claim rules. Before adding a new claim rule, delete any existing matching claim rule.

A CNS query with the compliance status filter set might take unusually long time to complete

The CNS QueryVolume API enables you to obtain information about the CNS volumes, such as volume health and compliance status. When you check the compliance status of individual volumes, the results are obtained quickly. However, when you invoke the CNS QueryVolume API to check the compliance status of multiple volumes, several tens or hundreds, the query might perform slowly.

Workaround: Avoid using bulk queries. When you need to get compliance status, query one volume at a time or limit the number of volumes in the query API to 20 or fewer. While using the query, avoid running other CNS operations to get the best performance.

New Deleted CNS volumes might temporarily appear as existing in the CNS UI

After you delete an FCD disk that backs a CNS volume, the volume might still show up as existing in the CNS UI. However, your attempts to delete the volume fail. You might see an error message similar to the following:

```
The object or item referred to could not be found.
```

Workaround: The next full synchronization will resolve the inconsistency and correctly update the CNS UI.

New Under certain circumstances, while a CNS operation fails, the task status appears as successful in the vSphere Client

This might occur when, for example, you use an incompliant storage policy to create a CNS volume. The operation fails, while the vSphere Client shows the task status as successful.

Workaround: The successful task status in the vSphere Client does not guarantee that the CNS operation succeeded. To make sure the operation succeeded, verify its results.

New Unsuccessful delete operation for a CNS persistent volume might leave the volume undeleted on the vSphere datastore

This issue might occur when the CNS Delete API attempts to delete a persistent volume that is still attached to a pod. For example, when you delete the Kubernetes namespace where the pod runs. As a result, the volume gets cleared from CNS and the CNS query operation does not return the volume. However, the volume continues to reside on the datastore and cannot be deleted through the repeated CNS Delete API operations.

Workaround: None.

vCenter Server and vSphere Client Issues

PR 3262556: vCenter upgrade fails with "VP last sync time not updated after waiting for 5 minutes after vCenter update"

In rare cases, during a vCenter upgrade, a race condition between vSphere API for Storage Awareness (VASA) providers might cause the upgrade to fail. In the `pod-service.log` file, you see an error such as `vSAN VP last sync time not updated after waiting for 5 minutes after vCenter update.`

This issue is resolved in this release. The fix prevents the race condition.

You do not see the VLAN ID in the port properties page of a VMkernel network adapter in the vSphere Client

In the vSphere Client, when you follow the path **Host > Add Networking**, after you select a VMkernel network adapter and an existing standard switch, in the **Port properties** page you might not see the VLAD ID. The issue occurs because the VLAN ID component is part of the `network-ui` module, which is lazy loaded and needs a trigger to refresh.

Workaround: Go to **Host > Configure > Networking > Virtual Switches** to trigger the loading of the `network ui` module and the VLAD ID appears.

Vendor providers go offline after a PNID change

When you change the vCenter IP address (PNID change), the registered vendor providers go offline.

Workaround: Re-register the vendor providers.

Cross vCenter migration of a virtual machine fails with an error

When you use cross vCenter vMotion to move a VM's storage and host to a different vCenter server instance, you might receive the error `The operation is not allowed in the current state.`

This error appears in the UI wizard after the Host Selection step and before the Datastore Selection step, in cases where the VM has an assigned storage policy containing host-based rules such as encryption or any other IO filter rule.

Workaround: Assign the VM and its disks to a storage policy without host-based rules. You might need to decrypt the VM if the source VM is encrypted. Then retry the cross vCenter vMotion action.

Storage Sensors information in Hardware Health tab shows incorrect values on vCenter UI, host UI, and MOB

When you navigate to **Host > Monitor > Hardware Health > Storage Sensors** on vCenter UI, the storage information displays either incorrect or unknown values. The same issue is observed on the host UI and the MOB path `"runtime.hardwareStatusInfo.storageStatusInfo"` as well.

Workaround: None.

vSphere UI host advanced settings shows the current product locker location as empty with an empty default

vSphere UI host advanced settings shows the current product locker location as empty with an empty default. This is inconsistent as the actual product location `symlink` is created and valid. This causes confusion to the user. The default cannot be corrected from UI.

Workaround: User can use the esxcli command on the host to correct the current product locker location default as below.

1. Remove the existing Product Locker Location setting with: "`esxcli system settings advanced remove -o ProductLockerLocation`"

2. Re-add the Product Locker Location setting with the appropriate default:

2.a. If the ESXi is a full installation, the default value is "`/locker/packages/vmtoolsRepo`" `export PRODUCT_LOCKER_DEFAULT="/locker/packages/vmtoolsRepo"`

2.b. If the ESXi is a PXEboot configuration such as autodeploy, the default value is: "`/vmtoolsRepo`" `export PRODUCT_LOCKER_DEFAULT="/vmtoolsRepo"`

Run the following command to automatically figure out the location: `export PRODUCT_LOCKER_DEFAULT=`readlink /productLocker``

Add the setting: `esxcli system settings advanced add -d "Path to VMware Tools repository" -o ProductLockerLocation -t string -s $PRODUCT_LOCKER_DEFAULT`

You can combine all the above steps in step 2 by issuing the single command:

```
esxcli system settings advanced add -d "Path to VMware Tools repository" -o
ProductLockerLocation -t string -s `readlink /productLocker`
```

Skyline Health page displays garbage characters

In the vSphere Client, when you navigate to vCenter Server or select an ESXi host in the vSphere Client navigator and click Monitor > Skyline Health, the page displays garbage characters in the following locales: Korean, Japanese, German and French.

Workaround: Switch to English locale.

Virtual Machine Management Issues

You cannot add or modify an existing network adapter on a virtual machine

If you try to add or modify an existing network adapter on a virtual machine, the Reconfigure Virtual Machine task might fail with an error such as `Cannot complete operation due to concurrent modification by another operation` in the vSphere Client. In the`/var/log/hostd.log` file of the ESXi host where the virtual machine runs, you see logs such as:

```
2020-07-28T07:47:31.621Z verbose hostd[2102259] [Originator@6876 sub=Vigor.Vmsvc.vm:/
vmfs/volumes/vsan:526bc94351cf8f42-41153841cab2f9d9/bad71f5f-d85e-a276-4cf6-246e965d7154/
interop_l2vpn_vmotion_VM_1.vmx] NIC: connection control message: Failed to connect virtual
device 'ethernet0'.
```

In the `vpxa.log` file, you see entries similar to: `2020-07-28T07:47:31.941Z info vpxa[2101759] [Originator@6876 sub=Default opID=opId-59f15-19829-91-01-ed] [VpxLRO] -- ERROR task-138 -- vm-13 -- vim.VirtualMachine.reconfigure: vim.fault.GenericVmConfigFault:`

Workaround: For each ESXi host in your cluster do the following:

1. Connect to the ESXi host by using SSH and run the command
   `esxcli system module parameters set -a -p dvfiltersMaxFilters=8192 -m dvfilter`
2. Put the ESXi host in Maintenance Mode.

3. Reboot the ESXi host.

For more information, see VMware knowledge base article 80399.

ESXi 6.5 hosts with AMD Opteron Generation 3 (Greyhound) processors cannot join Enhanced vMotion Compatibility (EVC) AMD REV E or AMD REV F clusters on a vCenter Server 7.0 Update 1 system

In vCenter Server 7.0 Update 1, vSphere cluster services, such as vSphere DRS and vSphere HA, run on ESX agent virtual machines to make the services functionally independent of vCenter Server. However, the CPU baseline for AMD processors of the ESX agent virtual machines have POPCNT SSE4A instructions, which prevents ESXi 6.5 hosts with AMD Opteron Generation 3 (Greyhound) processors to enable EVC mode AMD REV E and AMD REV F on a vCenter Server 7.0 Update 1 system.

Workaround: None

The postcustomization section of the customization script runs before the guest customization

When you run the guest customization script for a Linux guest operating system, the `precustomization` section of the customization script that is defined in the customization specification runs before the guest customization and the `postcustomization` section runs after that. If you enable Cloud-Init in the guest operating system of a virtual machine, the `postcustomization` section runs before the customization due to a known issue in Cloud-Init.

Workaround: Deactivate Cloud-Init and use the standard guest customization.

Group migration operations in vSphere vMotion, Storage vMotion, and vMotion without shared storage fail with error

When you perform group migration operations on VMs with multiple disks and multi-level snapshots, the operations might fail with the error `com.vmware.vc.GenericVmConfigFault Failed waiting for data. Error 195887167. Connection closed by remote host, possibly due to timeout.`

Workaround: Retry the migration operation on the failed VMs one at a time.

Deploying an OVF or OVA template from a URL fails with a 403 Forbidden error

The URLs that contain an HTTP query parameter are not supported. For example, `http://webaddress.com?file=abc.ovf` or the Amazon pre-signed S3 URLs.

Workaround: Download the files and deploy them from your local file system.

Importing or deploying local OVF files containing non-ASCII characters in their name might fail with an error

When you import local `.ovf` files containing non-ASCII characters in their name, you might receive `400 Bad Request Error` . When you use such `.ovf` files to deploy a virtual machine in the vSphere Client, the deployment process stops at 0%. As a result, you might receive `400 Bad Request Error` or `500 Internal Server Error.`

Workaround:

1. Remove the non-ASCII characters from the `.ovf` and `.vmdk` file names.
   - To edit the `.ovf` file, open it with a text editor.
   - Search the non-ASCII `.vmdk` file name and change it to ASCII.
2. Import or deploy the saved files again.

New The third level of nested objects in a virtual machine folder is not visible

Perform the following steps:

1. Navigate to a data center and create a virtual machine folder.

2. In the virtual machine folder, create a nested virtual machine folder.
3. In the second folder, create another nested virtual machine, virtual machine folder, vApp, or VM Template.

As a result, from the VMs and Templates inventory tree you cannot see the objects in the third nested folder.

Workaround: To see the objects in the third nested folder, navigate to the second nested folder and select the VMs tab.

vSAN file services operations fail on vSphere Lifecycle Manager-enabled clusters

During a change in the state of an ESXi host, vSAN file services operations might fail on vSphere Lifecycle Manager-enabled clusters due to a race condition with the vSphere ESX Agent Manager (EAM). The problem happens during upgrades and operations, such as power on or power off, booting, or when the host exits maintenance or standby mode. The race condition occurs when an endpoint has been unavailable before the change of state of the ESXi host. In such cases, the EAM starts a remediation process that cannot be resolved and fails operations from other services, such as the vSAN file services.

Workaround: Restart the vSphere ESX Agent Manager.

vSphere HA and Fault Tolerance Issues

VMs in a cluster might be orphaned after recovering from storage inaccessibility such as a cluster wide APD

Some VMs might be in orphaned state after cluster wide APD recovers, even if HA and VMCP are enabled on the cluster.

This issue might be encountered when the following conditions occur simultaneously:

- All hosts in the cluster experience APD and do not recover until VMCP timeout is reached.
- HA primary initiates failover due to APD on a host.
- Power on API during HA failover fails due to one of the following:
  - APD across the same host
  - Cascading APD across the entire cluster
  - Storage issues
  - Resource unavailability
- FDM unregistration and VCs steal VM logic might initiate during a window where FDM has not unregistered the failed VM and VC's host synchronization responds that multiple hosts are reporting the same VM. Both FDM and VC unregister the different registered copies of the same VM from different hosts, causing the VM to be orphaned.

Workaround: You must unregister and reregister the orphaned VMs manually within the cluster after the APD recovers.

If you do not manually reregister the orphaned VMs, HA attempts failover of the orphaned VMs, but it might take between 5 to 10 hours depending on when APD recovers.

The overall functionality of the cluster is not affected in these cases and HA will continue to protect the VMs. This is an anomaly in what gets displayed on VC for the duration of the problem.

vSphere Lifecycle Manager Issues

vSphere Lifecycle Manager and vSAN File Services cannot be simultaneously enabled on a vSAN cluster in vSphere 7.0 release

If vSphere Lifecycle Manager is enabled on a cluster, vSAN File Services cannot be enabled on the same cluster and vice versa. In order to enable vSphere Lifecycle Manager on a cluster, which has VSAN File Services enabled already, first deactivate vSAN File Services and retry the operation. Please note that if you transition to a cluster that is managed by a single image, vSphere Lifecycle Manager cannot be deactivated on that cluster.

Workaround: None.

You cannot edit the VMware vSphere Lifecycle Manager Update Download scheduled task

In the vSphere Client, when you navigate to a vCenter Server instance and select **Scheduled Tasks** under the **Configure** tab, if you select the **VMware vSphere Lifecycle Manager Update Download** task and click **Edit**, you cannot modify the existing settings.

Workaround: You can edit the **VMware vSphere Lifecycle Manager Update Download** task by following the steps in the topic Configure the vSphere Lifecycle Manager Automatic Download Task.

When a hardware support manager is unavailable, vSphere High Availability (HA) functionality is impacted

If hardware support manager is unavailable for a cluster that you manage with a single image, where a firmware and drivers addon is selected and vSphere HA is enabled, the vSphere HA functionality is impacted. You may experience the following errors.

- Configuring vSphere HA on a cluster fails.
- Cannot complete the configuration of the vSphere HA agent on a host: `Applying HA VIBs on the cluster encountered a failure.`
- Remediating vSphere HA fails: `A general system error occurred: Failed to get Effective Component map.`
- Disabling vSphere HA fails: Delete Solution task failed. `A general system error occurred: Cannot find hardware support package from depot or hardware support manager.`

Workaround:

- If the hardware support manager is temporarily unavailable, perform the following steps.

1. Reconnect the hardware support manager to vCenter Server.
2. Select a cluster from the Hosts and Cluster menu.
3. Select the Configure tab.
4. Under Services, click vSphere Availability.
5. Re-enable vSphere HA.

- If the hardware support manager is permanently unavailable, perform the following steps.

1. Remove the hardware support manager and the hardware support package from the image specification
2. Re-enable vSphere HA.
3. Select a cluster from the Hosts and Cluster menu.
4. Select the Updates tab.
5. Click Edit .
6. Remove the firmware and drivers addon and click Save.
7. Select the Configure tab.
8. Under Services, click vSphere Availability.
9. Re-enable vSphere HA.

I/OFilter is not removed from a cluster after a remediation process in vSphere Lifecycle Manager

Removing I/OFilter from a cluster by remediating the cluster in vSphere Lifecycle Manager, fails with the following error message: `iofilter XXX already exists` . The iofilter remains listed as installed.

Workaround:

1. Call IOFilter API `UninstallIoFilter_Task` from the vCenter Server managed object (IoFilterManager).
2. Remediate the cluster in vSphere Lifecycle Manager.
3. Call IOFilter API `ResolveInstallationErrorsOnCluster_Task` from the vCenter Server managed object (IoFilterManager) to update the database.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, disabling and re-enabling vSphere HA causes a vSphere HA error state

Disabling and re-enabling vSphere HA during remediation process of a cluster, may fail the remediation process due to vSphere HA health checks reporting that hosts don't have vSphere HA VIBs installed. You may see the following error message: `Setting desired image spec for cluster failed.`

Workaround: After the cluster remediation operation has finished, deactivate and re-enable vSphere HA for the cluster.

Checking for recommended images in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the recommendation generation task could take more than an hour to finish or may appear to hang. The completion time for the recommendation task depends on the number of devices configured on each host and the number of image candidates from the depot that vSphere Lifecycle Manager needs to process before obtaining a valid image to recommend.

Workaround: None.

Checking for hardware compatibility in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the validation report generation task could take up to 30 minutes to finish or may appear to hang. The completion time depends on the number of devices configured on each host and the number of hosts configured in the cluster.

Workaround: None

Incomplete error messages in non-English languages are displayed, when remediating a cluster in vSphere Lifecycle Manager

You can encounter incomplete error messages for localized languages in the vCenter Server user interface. The messages are displayed, after a cluster remediation process in vSphere Lifecycle Manager fails. For example, your can observe the following error message.

The error message in English language: `Virtual machine 'VMC on DELL EMC -FileServer' that runs on cluster 'Cluster-1' reported an issue which prevents entering maintenance mode: Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

The error message in French language: `La VM « VMC on DELL EMC -FileServer », située sur le cluster « {Cluster-1} », a signalé un problème empêchant le passage en mode de maintenance : Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

Workaround: None.

When you convert a cluster that uses baselines to a cluster that uses a single image, a warning is displayed that vSphere HA VIBs will be removed

Converting a vSphere HA enabled cluster that uses baselines to a cluster that uses a single image, may result a warning message displaying that `vmware-fdm` component will be removed.

Workaround: This message can be ignored. The conversion process installs the `vmware-fdm` component.

If vSphere Update Manager is configured to download patch updates from the Internet through a proxy server, after upgrade to vSphere 7.0 that converts Update Manager to vSphere Lifecycle Manager, downloading patches from VMware patch repository might fail

In earlier releases of vCenter Server you could configure independent proxy settings for vCenter Server and vSphere Update Manager. After an upgrade to vSphere 7.0, vSphere Update Manager service becomes part of the vSphere Lifecycle Manager service. For the vSphere Lifecycle Manager service, the proxy settings are configured from the vCenter Server appliance settings. If you had configured Update Manager to download patch updates from the Internet through a proxy server but the vCenter Server appliance had no proxy setting configuration, after a vCenter Server upgrade to version 7.0, the vSphere Lifecycle Manager fails to connect to the VMware depot and is unable to download patches or updates.

Workaround: Log in to the vCenter Server Appliance Management Interface, https://*vcenter-server-appliance-FQDN-or-IP-address*:5480, to configure proxy settings for the vCenter Server appliance and enable vSphere Lifecycle Manager to use proxy.

If you use a Java client to review remediation tasks, you cannot extract the results from the remediation operations

If you use a Java client to review remediation tasks, extracting the results might fail with a `ConstraintValidationException` error. The issue occurs when an ESXi host fails to enter maintenance mode during the remediation and gets a status SKIPPED, but at the same time wrongly gets an In Progress flag for the consecutive remediation operations. This causes the `ConstraintValidationException` error on the Java Clients and you cannot extract the result of the remediation operation.

Workaround: Fix the underlying issues that prevent ESXi hosts to enter Maintenance Mode and retry the remediation operation.

The general vSphere Lifecycle Manager depot and local depots in Remote Office and Branch Office (ROBO) deployments might not be in sync

ROBO clusters that have limited or no access to the Internet or limited connectivity to vCenter Server can download an image from a depot that is local for them instead of accessing the vSphere Lifecycle Manager depot in vCenter Server. However, vSphere Lifecycle Manager generates software recommendations in the form of pre-validated images only on a central level and a recommended image content might not be available at a depot override.

Workaround: If you decide to use a recommended image, make sure the content between depot overrides and the central depot are in sync.

Cluster remediation by using the vSphere Lifecycle Manager might fail on ESXi hosts with enabled lockdown mode

If a cluster has ESXi hosts with enabled lockdown mode, remediation operations by using the vSphere Lifecycle Manager might skip such hosts. In the log files, you see messages such as `Host scan task failed` and `com.vmware.vcIntegrity.lifecycle.EsxImage.UnknownError An unknown error occurred while performing the operation.`.

Workaround: Add the root user to the exception list for lockdown mode and retry the cluster remediation.

You cannot use an ESXi image with OEM content to create clusters by using vSphere Lifecycle Manager workflows after an update

When you update an ESXi image with OEM content, for example Dell ESXi 7.0 Update 2a to Dell ESXi 7.0 Update 3d, some reserved VIBs, such that are present in the VMware base image but overridden by async VIBs packaged by the OEM, might be deleted. The same issue might occur after updating your system by using a non-critical baseline and then update to a higher version by using an ESXi image with OEM content. For example, if you update to 7.0 Update 2 by using a non-critical baseline and then update to 7.0 Update 3 by using a Dell ESXi 7.0 Update 3 image, reserved VIBs might also be deleted. As a result, you cannot use ESXi hosts with the updated version to create a vSphere Lifecycle Manager cluster managed by a single image. The operation fails and in the backtrace, you see errors such as:

```
2021-11-24T09:42:49Z lifecycle: 2101166: HostSeeding:956 ERROR Extract depot failed:
('VMW_bootbank_bnxtroce_216.0.58.0-23vmw.703.0.0.18644231', 'Failed to add reserved
VIB VMW_bootbank_bnxtroce_216.0.58.0-23vmw.703.0.0.18644231: not found in the reserved
VIB cache storage')2021-11-24T09:42:50Z lifecycle: 2101166: imagemanagerctl:373 ERROR
Extract depot failed.021-11-24T09:42:50Z lifecycle: 2101166: imagemanagerctl:152 ERROR
[ReservedVibExtractError] ('VMW_bootbank_bnxtroce_216.0.58.0-23vmw.703.0.0.18644231',
'Failed to add reserved VIB VMW_bootbank_bnxtroce_216.0.58.0-23vmw.703.0.0.18644231: not
found in the reserved VIB cache storage')
```

Workaround: Use interactive or scripted upgrade instead of vSphere Lifecycle Manager workflows.

After you upgrade to vCenter Server 7.0.0b, in the vSphere Lifecycle Manager home view in the vSphere Client, you do not see the Show only rollup updates toggle button

In vCenter Server 7.0.0b, you can use the **Show only rollup updates** toggle button to filter and select patches that you want to include in a baseline when you use the vSphere Lifecycle Manager.

The button is available in the **Updates** tab on the **Lifecycle Manager** pane, **Menu** > **Lifecycle Manager**, which is the vSphere Lifecycle Manager home view in the vSphere Client. The button is also available in the **Select Patches Manually** page on the **Baselines** tab in the **Create Baseline** wizard, which opens when you select **New** > **Baseline**.

However, the **Show only rollup updates** toggle button might not be visible after you upgrade to vCenter Server 7.0.0b.

Workaround: After an upgrade to vCenter Server 7.0.0b, restart the vSphere Client. For more information, see Start, Stop, and Restart Services.

The Show only rollup updates toggle button is always turned on when you open a tab in the vSphere Lifecycle Manager home view in the vSphere Client

In vCenter Server 7.0.0b, you can use the **Show only rollup updates** toggle button to filter and select patches that you want to include in a baseline when you use the vSphere Lifecycle Manager.

The button is available in the **Updates** tab on the **Lifecycle Manager** pane, **Menu** > **Lifecycle Manager**, which is the vSphere Lifecycle Manager home view in the vSphere Client. The button is also available in the **Select Patches Manually** page on the **Baselines** tab in the **Create Baseline** wizard, which opens when you select **New** > **Baseline**.

However, the toggle button appears always turned on when you navigate to either of the **Updates** tab or the **Select Patches Manually** page. Even if you turn off the button when navigating away from the tab or page, it appears still turned on the next time you open them.

Workaround: None

When you use the Update Planner, in the vSphere Client you might see Unexpected error occurred while fetching the updates

When you use Update Planner, which is part of vSphere Lifecycle Manager, used to facilitate vCenter Server updates, you might see the following error in the vSphere Client:

```
Unexpected error occurred while fetching the updates
```

The issue occurs when you use a custom HTTPS port that prevents you from running interoperability reports by using the vSphere Client.

Workaround: Manually invoke the API. For more details, see the vSphere Automation API.

Miscellaneous Issues

When applying a host profile with version 6.5 to a ESXi host with version 7.0, the compliance check fails

Applying a host profile with version 6.5 to a ESXi host with version 7.0, results in Coredump file profile reported as not compliant with the host.

Workaround: There are two possible workarounds.

1. When you create a host profile with version 6.5, set an advanced configuration option VMkernel.Boot.autoCreateDumpFile to false on the ESXi host.
2. When you apply an existing host profile with version 6.5, add an advanced configuration option VMkernel.Boot.autoCreateDumpFile in the host profile, configure the option to a fixed policy, and set value to false.

Cannot migrate container volume due to insufficient space

The Migrate volume dialog in vSphere Client considers the current size of container volumes and the free space available on the target datastores. If the free space of a datastore is less than the volume size, then you cannot select the datastore for migration. vSphere preserves the storage policy as it migrates the volume, but the file size of the volume might change depending on the destination datastore type and its supported features. The vSphere Client might show the datastore has insufficient space to perform the migration, even though enough space is available.

Workaround: None

The Actions drop-down menu does not contain any items when your browser is set to language different from English

When your browser is set to language different from English and you click the **Switch to New View** button from the virtual machine **Summary** tab of the vSphere Client inventory, the **Actions** drop-down menu in the **Guest OS** panel does not contain any items.

Workaround: Select the **Actions** drop-down menu on the top of the virtual machine page.

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit minor throughput degradation when Dynamic Receive Side Scaling (DYN_RSS) or Generic RSS (GEN_RSS) feature is turned on

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit less than 5 percent throughput degradation when DYN_RSS and GEN_RSS feature is turned on, which is unlikely to impact normal workloads.

Workaround: You can deactivate DYN_RSS and GEN_RSS feature with the following commands:

```
# esxcli system module parameters set -m nmlx5_core -p "DYN_RSS=0 GEN_RSS=0"
# reboot
```

RDMA traffic between two VMs on the same host might fail in PVRDMA environment

In a vSphere 7.0 implementation of a PVRDMA environment, VMs pass traffic through the HCA for local communication if an HCA is present. However, loopback of RDMA traffic does not work on qedrntv driver. For instance, RDMA Queue Pairs running on VMs that are configured under same uplink port cannot communicate with each other.

In vSphere 6.7 and earlier, HCA was used for local RDMA traffic if SRQ was enabled. vSphere 7.0 uses HCA loopback with VMs using versions of PVRDMA that have SRQ enabled with a minimum of HW v14 using RoCE v2.

The current version of Marvell FastLinQ adapter firmware does not support loopback traffic between QPs of the same PF or port.

Workaround: Required support is being added in the out-of-box driver certified for vSphere 7.0. If you are using the inbox qedrntv driver, you must use a 3-host configuration and migrate VMs to the third host.

Unreliable Datagram traffic QP limitations in qedrntv driver

There are limitations with the Marvell FastLinQ qedrntv RoCE driver and Unreliable Datagram (UD) traffic. UD applications involving bulk traffic might fail with qedrntv driver. Additionally, UD QPs can only work with DMA Memory Regions (MR).

Physical MRs or FRMR are not supported. Applications attempting to use physical MR or FRMR along with UD QP fail to pass traffic when used with qedrntv driver. Known examples of such test applications are `ibv_ud_pingpong` and `ib_send_bw`.

Standard RoCE and RoCEv2 use cases in a VMware ESXi environment such as iSER, NVMe-oF (RoCE) and PVRDMA are not impacted by this issue. Use cases for UD traffic are limited and this issue impacts a small set of applications requiring bulk UD traffic.

Marvell FastLinQ hardware does not support RDMA UD traffic offload. In order to meet the VMware PVRDMA requirement to support GSI QP, a restricted software only implementation of UD QP support was added to the qedrntv driver. The goal of the implementation is to provide support for control path GSI communication and is not a complete implementation of UD QP supporting bulk traffic and advanced features.

Since UD support is implemented in software, the implementation might not keep up with heavy traffic and packets might be dropped. This can result in failures with bulk UD traffic.

Workaround: Bulk UD QP traffic is not supported with qedrntv driver and there is no workaround at this time. VMware ESXi RDMA (RoCE) use cases like iSER, NVMe, RDMA and PVRDMA are unaffected by this issue.

Servers equipped with QLogic 578xx NIC might fail when frequently connecting or disconnecting iSCSI LUNs

If you trigger QLogic 578xx NIC iSCSI connection or disconnection frequently in a short time, the server might fail due to an issue with the qfle3 driver. This is caused by a known defect in the device's firmware.

Workaround: None.

ESXi might fail during driver unload or controller disconnect operation in Broadcom NVMe over FC environment

In Broadcom NVMe over FC environment, ESXi might fail during driver unload or controller disconnect operation and display an error message such as: `@BlueScreen: #PF Exception 14 in world 2098707:vmknvmeGener IP 0x4200225021cc addr 0x19`

Workaround: None.

ESXi does not display OEM firmware version number of i350/X550 NICs on some Dell servers

The inbox ixgben driver only recognizes firmware data version or signature for i350/X550 NICs. On some Dell servers the OEM firmware version number is programmed into the OEM package version region, and the inbox ixgben driver does not read this information. Only the 8-digit firmware signature is displayed.

Workaround: To display the OEM firmware version number, install async ixgben driver version 1.7.15 or later.

X710 or XL710 NICs might fail in ESXi

When you initiate certain destructive operations to X710 or XL710 NICs, such as resetting the NIC or manipulating VMKernel's internal device tree, the NIC hardware might read data from non-packet memory.

Workaround: Do not reset the NIC or manipulate vmkernel internal device state.

NVMe-oF does not guarantee persistent VMHBA name after system reboot

NVMe-oF is a new feature in vSphere 7.0. If your server has a USB storage installation that uses vmhba30+ and also has NVMe over RDMA configuration, the VMHBA name might change after a system reboot. This is because the VMHBA name assignment for NVMe over RDMA is different from PCIe devices. ESXi does not guarantee persistence.

Workaround: None.

Backup fails for vCenter database size of 300 GB or greater

If the vCenter database size is 300 GB or greater, the file-based backup will fail with a timeout. The following error message is displayed: `Timeout! Failed to complete in 72000 seconds`

Workaround: None.

A restore of vCenter Server 7.0 which is upgraded from vCenter Server 6.x with External Platform Services Controller to vCenter Server 7.0 might fail

When you restore a vCenter Server 7.0 which is upgraded from 6.x with External Platform Services Controller to vCenter Server 7.0, the restore might fail and display the following error: `Failed to retrieve appliance storage list`

Workaround: During the first stage of the restore process, increase the storage level of the vCenter Server 7.0. For example if the vCenter Server 6.7 External Platform Services Controller setup storage type is small, select storage type large for the restore process.

Enabled SSL protocols configuration parameter is not configured during a host profile remediation process

`Enabled SSL protocols` configuration parameter is not configured during a host profile remediation and only the system default protocol `tlsv1.2` is enabled. This behavior is observed for a host profile with version 7.0 and earlier in a vCenter Server 7.0 environment.

Workaround: To enable TLSV 1.0 or TLSV 1.1 SSL protocols for SFCB, log in to an ESXi host by using SSH, and run the following ESXCLI command: `esxcli system wbem -P <protocol_name>`

Unable to configure Lockdown Mode settings by using Host Profiles

Lockdown Mode cannot be configured by using a security host profile and cannot be applied to multiple ESXi hosts at once. You must manually configure each host.

Workaround: In vCenter Server 7.0, you can configure Lockdown Mode and manage Lockdown Mode exception user list by using a security host profile.

When a host profile is applied to a cluster, Enhanced vMotion Compatibility (EVC) settings are missing from the ESXi hosts

Some settings in the VMware config file `/etc/vmware/config` are not managed by Host Profiles and are blocked, when the config file is modified. As a result, when the host profile is applied to a cluster, the EVC settings are lost, which causes loss of EVC functionalities. For example, unmasked CPUs can be exposed to workloads.

Workaround: Reconfigure the relevant EVC baseline on cluster to recover the EVC settings.

Using a host profile that defines a core dump partition in vCenter Server 7.0 results in an error

In vCenter Server 7.0, configuring and managing a core dump partition in a host profile is not available. Attempting to apply a host profile that defines a core dump partition, results in the following error: `No valid coredump partition found.`

Workaround: None. In vCenter Server 7.0., Host Profiles supports only file-based core dumps.

You cannot paste by right clicking in the vi editor

If you use the vi text editor on a vCenter Server Appliance instance, you cannot paste previously copied content by right clicking. Instead, the vi editor changes mode to Visual.

Workaround: From the vCenter Server Appliance shell, run the command`/usr/bin/sed -i.bak -E '2alet skip_defaults_vim=1' /etc/vimrc`.

HTTP requests from certain libraries to vSphere might be rejected

The HTTP reverse proxy in vSphere 7.0 enforces stricter standard compliance than in previous releases. This might expose pre-existing problems in some third-party libraries used by applications for SOAP calls to vSphere.

If you develop vSphere applications that use such libraries or include applications that rely on such libraries in your vSphere stack, you might experience connection issues when these libraries send HTTP requests to VMOMI. For example, HTTP requests issued from vijava libraries can take the following form:

```
POST /sdk HTTP/1.1
SOAPAction
Content-Type: text/xml; charset=utf-8
User-Agent: Java/1.8.0_221
```

The syntax in this example violates an HTTP protocol header field requirement that mandates a colon after SOAPAction. Hence, the request is rejected in flight.

Workaround: Developers leveraging noncompliant libraries in their applications can consider using a library that follows HTTP standards instead. For example, developers who use the vijava library can consider using the latest version of the yavijava library instead.

SNMP dynamic firewall ruleset is modified by Host Profiles during a remediation process

The SNMP firewall ruleset is a dynamic state, which is handled during runtime. When a host profile is applied, the configuration of the ruleset is managed simultaneously by Host Profiles and SNMP, which can modify the firewall settings unexpectedly.

Workaround: There are two possible workarounds.

- To allow the ruleset to manage itself dynamically, exclude the SNMP firewall ruleset option in the configuration of the host profile.
- To proceed with the double management of the ruleset, when needed, correct the firewall ruleset state.

You might see a dump file when using Broadcom driver lsi_msgpt3, lsi_msgpt35 and lsi_mr3

When using the lsi_msgpt3, lsi_msgpt35 and lsi_mr3 controllers, there is a potential risk to see dump file lsuv2-lsi-drivers-plugin-util-zdump. There is an issue when exiting the storelib used in this plugin utility. There is no impact on ESXi operations, you can ignore the dump file.

Workaround: You can safely ignore this message. You can remove the lsuv2-lsi-drivers-plugin with the following command:

```
esxcli software vib remove -n lsuv2-lsiv2-drivers-plugin
```

You might see reboot is not required after configuring SR-IOV of a PCI device in vCenter, but device configurations made by third party extensions might be lost and require reboot to be re-applied.

In ESXi 7.0, SR-IOV configuration is applied without a reboot and the device driver is reloaded. ESXi hosts might have third party extensions perform device configurations that need to run after the device driver is loaded during boot. A reboot is required for those third party extensions to re-apply the device configuration.

Workaround: You must reboot after configuring SR-IOV to apply third party device configurations.

You see black or grey zones in the background of a parent window in the Direct Console User Interface (DCUI) after a child window closes

In the DCUI, when you close a child window by pressing the ESC or Enter keys, or the **Cancel** or **OK** buttons, the parent window appearance might change. The background color changes to grey or black for some part of the parent window. However, all required information from the DCUI is properly displayed and all operations performed in the DCUI complete successfully.

Workaround: Wait for 1 minute without refreshing the current window in the DCUI or pressing any key.

Backup Issues

If you use the NFS and SMB protocols for file-based backup of vCenter Server, the backup fails after an update from vCenter Server 7.x to vCenter Server 7.0 Update 1

If you use the Network File System (NFS) and Server Message Block (SMB) protocols for file-based backup of vCenter Server, the backup fails after an update from an earlier version of vCenter Server 7.x to vCenter Server 7.0 Update 1. In the `applmgmt.log` , you see an error message such as `Failed to mount the remote storage` . The issue occurs because of Linux kernel updates that run during the patch process. The issue does not occur on fresh installations of vCenter Server 7.0 Update 1.

Workaround: Reboot the vCenter Server appliance after the update is complete.

Microsoft Active Directory Federation Services (ADFS) logins might fail after restoring a vCenter Server Appliance

If you manually add a certificate to the vCenter Server JRE truststore or modify the `/etc/hosts` file when setting up ADFS, the changes are not preserved after restoring and might cause ADFS logins to fail.

Workaround: Add the ADFS certificate to the vCenter Server JRE truststore after restoring your vCenter Server Appliance. For more information, see Import the Trusted Certificate of an External Identity Provider. Add the necessary host name mappings back to the `/etc/hosts` file after restoring your vCenter Server Appliance.

vSAN Issues

Higher than actual vSAN storage pool free space estimate might lead to unexpected storage shortages

The `freeSpace` parameter of a vSAN storage pool might not exclude disks with errors and display the unused space estimate as higher than the actual. As a result, you might see unexpected storage shortages. This issue only affects vSAN storage pools.

Workaround: Manually compute the storage capacity by disregarding the `freeSpace` value of disks with errors from the overall storage capacity provided by the `freeSpace` parameter of the storage pool.

Server Configuration Issues

You see a message Error retrieving when trying to view the status of Key Management Server (KMS) instances in the vSphere Client

In the vSphere Client, you might see a message `Error retrieving` for several minutes when trying to view Key Management Server (KMS) instances. The issue occurs when a KMS instance in a standard key provider loses connectivity. Until all network requests to the affected KMS time out, which takes around 4 minutes, you cannot see the status of any KMS instance in your system, only the error message for the key provider. After the timeout, you can see the status of all KMS instances.

Workaround: If you see the Error retrieving message, wait for 4 minutes.

Due to a default timeout setting of 2 minutes, log in to vCenter instances in Enhanced Linked Mode takes long when any of the vCenters is down

When you have a number of vCenter instances in Enhanced Linked Mode, if one of the instances is down for some reason, such as maintenance, log in to the other instances might take up to 2 minutes, which is the default timeout setting. Changing the timeout property that specifies the wait time for log in to linked vCenter instances is a complex task that requires manually editing the `LinkedVcGroup.login.timeout` property located in `vim-commons-vsphere.properties` . To simlify the task, starting with vCenter Server 7.0 Update 3l, the

setting `LinkedVcGroup.login.timeout=120000` moves from `vim-commons-vsphere.properties` to the `webclient.properties` file. Editing this option allows you to reduce the wait time so that if one of the vCenter logins is taking more time, it does not affect the log in time for other instances.

Workaround: Edit `/etc/vmware/vsphere-ui/webclient.properties` and change the value of `LinkedVcGroup.login.timeout` from `120000` to a smaller value in milliseconds, but consider that a value of `<= 0` is an infinite timeout.

VMware vCenter Server 7.0 Update 3v Release Notes

This document contains the following sections

- Introduction
- What's New
- Upgrade Notes
- Patches Contained in This Release
- Resolved Issues
- Known Issues
- Known Issues from Prior Releases

Introduction

VMware vCenter Server 7.0 Update 3v | 20 MAY 2025 | ISO Build 24730281 Check for additions and updates to these release notes.

What's New

- For vCenter Server 7.0 Update 3v updates, see the **Resolved Issues** and **Known Issues** sections.
- For vSphere Supervisor updates, see the vSphere Supervisor Release Notes.
- For Photon OS updates, see VMware vCenter Server Appliance Photon OS Security Patches.

This release resolves CVE-2025-41225. For more information on this vulnerability and its impact on Broadcom products, see VMSA-2025-0010.

Prefix-Based MAC Address Allocation by the vCenter GUI Installer and CLI:

vCenter 7.0 Update 3v adds the option to use prefix-based allocation to specify an OUI other than the default one 00:50:56 by Broadcom, or to introduce Locally Administered MAC Addresses (LAA) for a larger address space, by using either the vCenter GUI installer or the CLI installer. After deploying a vCenter instance, you can use the vSphere Client to switch between the available allocation schemes.

Upgrade Notes

Upgrading from vCenter 7.0 Update 3v to vCenter 8.0 Update 3e is not supported due to back-in-time release restrictions. For more information, see KB 67077.

Patches Contained in This Release

Patch for VMware vCenter Server Appliance 7.0 Update 3v

Download Filename	VMware-vCenter-Server-Appliance-7.0.3.02400-24730281-patch-FP.iso
Build	24730281
Download Size	6686.0 MB

PRs fixed	3404100, 3404108, 3471234, 3503319, 3484455, 3484244, 3245536, 3426087, 3473337, 3407726, 3384385, 3418166, 3367090, 3444766, 3468763, 3486798, 3419045
CVEs	CVE-2025-41225

Download and Installation

Log in to the Broadcom Support Portal to download this patch.

For download instructions for earlier releases, see Download Broadcom products and software.

For more information on using the vCenter Server shells, see VMware knowledge base article 2100508.

For more information on patching vCenter Server, see Patching the vCenter Server Appliance.

For more information on staging patches, see Stage Patches to vCenter Server Appliance.

For more information on installing patches, see Install vCenter Server Appliance Patches.

For more information on patching using the Appliance Management Interface, see Patching the vCenter Server by Using the Appliance Management Interface.

Resolved Issues

vCenter and vSphere Client Issues

PR 3404100: vCenter performance stats shows incorrect aggregate values when the data is rolled up to the daily partition

Without date rounding logic, the partition index might start at a random hour instead of 00:00:00, leading to incorrect aggregate values when the data is rolled up to the daily partition.

This issue is resolved in this release.

PR 3404108: Rollup processing of performance stats data in vCenter occurs only by the average rollup type

In vCenter performance statistics, you see only the average value of each duration, regardless if the rollup type is different, such as summation or latest.

This issue is resolved in this release.

PR 3471234: Smart card authentication on vCenter intermittently fails with the error "Unable to validate submitted credentials"

The Certificate Revocation List (CRL) cache updates hourly and if you log in to vCenter by using a smart card during such an hourly cycle in which the old CRL is expired but no new CRL is downloaded, the login fails. Since this is a corner

case, smart card authentication on vCenter intermittently fails and in the vSphere Client, you see the error `Unable to validate submitted credentials.`

This issue is resolved in this issue.

PR 3503319: The vpxd service fails because the Guest OS customization API requires IPv4 settings

When you use API to create a Guest Customization Specification and customize the guest OS of a virtual machine, you might need to enter IPv4 settings in the specification or the vpxd service fails with a core dump.

This issue is resolved in this release.

PR 3484455: Distributed Resource Scheduler (DRS) fails to migrate an encrypted VM with an error for missing [Cryptographic operations > Migrate] privileges

In some cases, when DRS schedules to migrate an encrypted VM, it might use the context of a user without `Cryptographer.Migrate` privilege and migration fails with an error in the vSphere Client such as: `Permission to perform this operation was denied. You do not hold privileges "virtual machine vm-xx : [Cryptographic operations > Migrate].`

In the vpxd.log, you see error messages such as:

`YYYY-MM-DDThh:mm:ss.472Z info vpxd[06061] [Originator@6876 sub=drsExec opID=<op_id>] Executing DRM recommended vMotion in [vim.ClusterComputeResource:domain-c<id>,esxi_name], migrating [vim.VirtualMachine:vm-<vm_id>,vm_name] from vim.HostSystem:host-<src_id> to vim.HostSystem:host-<dstn_id>……..`

`YYYY-MM-DDThh:mm:ss.494Z info vpxd[06061] [Originator@6876 sub=pbm opID=<op_id>-01] pre migrate callback is skipped - for cached from pre migrate check reason`

`YYYY-MM-DDThh:mm:ss.494Z warning vpxd[06061] [Originator@6876 sub=CryptoManager opID=<op_id>-01] The session xx-yy-zz of user DOMAIN\user_name does not have privilege Cryptographer.Migrate on entity [vim.VirtualMachine:vm-<vm_id>,vm_name].`

This issue is resolved in this release.

PR 3484244: A rare race condition might cause repeating failovers due to a failure of the vCenter vpxd service or the vSphere Client becoming unresponsive

A rare race condition during a VAPI call from the vpxd service to a virtual machine that coincides with the deletion of a `VirtualMachine` object might cause the vpxd service to fail. As a result, you see repeating failovers or the vSphere Client might become unresponsive.

This issue is resolved in this release.

PR 3245536: When an ESXi host has multiple management IP addresses, in some vSphere Client workflows you might see a "Host not reachable" error

You can assign multiple management IP addresses to a single ESXi host and it is not necessary that all IP addresses are reachable from vCenter at any time. However, if vCenter picks a currently unreachable IP during a workflow that you run from the vSphere Client, such as a remediation precheck, the task might fail with a `Host not reachable` error.

This issue is resolved in this release.

Networking Issues

PR 3351967: Stale NSX properties from ESXi hosts that vCenter might use can cause various networking issues

In some cases, vCenter might retrieve NSX properties from ESXi hosts, save them on the vCenter database and push these NSX properties back to ESXi hosts in various scenarios that can cause the following issues:

1. A virtual switch gets out of sync because vCenter pushes stale NSX properties to an ESXi host.

2. You cannot remove the NSX VIB after you remove a transport node, because vCenter pushes NSX properties back to the virtual switch.
3. After an ESXi host reboot, vCenter feeds stale NSX properties back to the virtual switch.
4. NSX cannot start on a virtual switch due to stale NSX properties.

Logs are different in each case, but you can confirm the issue by checking the `VPX_DVS_BLOB` table in the vCenter DB. If you see NSX properties in the `VPX_DVS_BLOB` table, the issue exists. Look for properties such as:

```
com.vmware.nsx.kcp.enable

com.vmware.nsx.spf.enabled

com.vmware.nsx.vdl2.enabled

com.vmware.vswitch.disabled

com.vmware.host.feature.container

com.vmware.nsx.ens.loadbal

com.vmware.nsx.ens.overlayl2flow
```

This issue is resolved in this release.

PR 3426087: You see duplicate routes in the Netplan configuration file after guest OS customization on Ubuntu VMs

For Ubuntu releases that support the Netplan utility for configuring networking on a Linux system, when you deploy an Ubuntu VM and customize it with both IPv4 and IPv6 gateways, the Netplan configuration file `/etc/netplan/99-netcfg-vmware.yaml` of the guest OS contains two route sections under a single network interface.

This issue is resolved in this release. With the fix, customizing an Ubuntu VM with both IPv4 and IPv6 gateways creates a single route section for each NIC in the Netplan configuration file, and adds the corresponding IPv4 and IPv6 gateways of the NIC to its route section.

PR 3473337: In the vSphere Client, you still see an NSX overlay segment after deleting it from the NSX Manager

When adding NSX port groups on a vCenter system, vCenter uses an API call to push the port groups to ESXi hosts, but in some cases the call does not complete on all hosts, if a host is temporarily disconnected for example. As a result, from vCenter perspective, all port groups exist, but from ESXi hosts perspective, some might not exist. Consequently, when you try to delete an NSX overlay segment from the NSX Manager, it still shows in the vSphere Client, because not all port groups can be removed.

This issue is resolved in this release.

PR 3407726: If the Key Management Server (KMS) sends a response not in Key Management Interoperability Protocol (KMIP) format, the vpxd service might fail

In rare cases, KMS might send a response that does not follow the KMIP protocol, which leads to the use of an invalid address in analyzing the response and in turn causes the vpxd service to fail.

This issue is resolved in this release.

PR 3384385: The vpxd service fails after the Mobility Agent (MA) host for VMware HCX is reconnected or redeployed

When you reconnect or redeploy the MA service, which is the data proxy for vSphere vMotion in HCX between onprem and cloud migrations, as a host object in vCenter, the vpxd service might fail due to duplicate entries in the vCenter database. In the vpxd log, you see messages such as `ODBC error: (23505) - ERROR: duplicate key value violates unique constraint "pk_vpx_nw_assignment.`

This issue is resolved in this release.

PR 3418166: You don't see newly created NSX Distributed Virtual port groups on some ESXi hosts

When multiple ESXi hosts join a new transport zone, a race condition in the vCenter host sync handler might cause some ESXi hosts to fail saving the new transport zones configuration. As a result, you don't see newly created NSX Distributed Virtual port groups in the new transport zone on such hosts.

This issue is resolved in this release.

Miscellaneous Issues

PR 3367090: Changes in the authorization roles on an ESXi host are not persistent across reboots

Due to an issue with saving changes to the underlying storage, modifications of the authorization roles on an ESXi host, such as adding a privilege, might not persist across reboots.

This issue is resolved in this release.

PR 3444766: vCenter CPU utilization reaches 100% and the vCenter system becomes slow or unresponsive

After several days of uptime, due to an issue with the Apache HttpCore library, the vCenter CPU utilization by the `vsphere-ui` service might reach 100% and the vCenter system becomes slow or unresponsive.

This issue is resolved in this release.

Upgrade Issues

PR 3468763: During upgrade, the prefix-based MAC allocation scheme configuration is not migrated to the target vCenter

Due to an issue with the configuration path, the prefix-based MAC allocation scheme configuration might not be migrated to the target vCenter during an upgrade.

This issue is resolved in this release.

PR 3486798: ESXi host update or upgrade fails with errors for running out of memory

When an ESXi host enters maintenance mode, it might not clear the resource pool mirror and reservations for the mirror before the evacuations of the last VM are not freed. This leads to insufficient memory being available for upgrade or update, especially if the last VM that is evacuated has a large reservation, such as tens of GBs. In the backtrace, you see an error such as `Admission failure in path: host:system:kernel:stagebootbank.`

This issue is resolved in this release.

vSAN Issues

PR 3419045: vSAN tasks fail with NotSupported exception

In vSAN HCI with datastore sharing environment (formerly HCI Mesh), a vSAN datastore that belongs to one vSAN cluster can be mounted on hosts of other clusters. Such hosts provide only compute and not storage, and might not even have vSAN active. In the Site Recovery Manager reprotect workflow, if a certain API call is made to a host with no active vSAN, the call ends with a `NotSupported` exception. If such a call is made to a vSAN-enabled compute-only host, then you see no error, but the call does not return any results.

This issue is resolved in this release. The fix makes sure API calls for the SRM reprotect workflow to pick up only hosts with active vSAN.

Known Issues

vCenter and vSphere Client Issues

If the vCenter certificate mode is set to thumbprint or custom, you cannot export logs by using the vSphere Client

If for some reason the advanced setting `vpxd.certmgmt.mode` in a vCenter instance is set to `thumbprint` , which is recommended only as a fallback option, or `custom` , you cannot export logs by using the vSphere Client.

Workaround: Change the `vpxd.certmgmt.mode` setting to `vmca` .

You cannot upload log packages to a VMware service request by using the vSphere Client

You cannot upload log packages to a VMware service request by navigating in the vSphere Client to **Administration > Support > Upload File to Service Request**. Instead, you see a link to a KB article that provides steps to upload log bundles in the Broadcom Support Portal. This is expected.

Workaround: Follow the steps in Uploading files to cases on the Broadcom Support Portal.

Security Issues

Update Manager Download Service (UMDS) stores proxy passwords in plain text

When UMDS accesses a VMware online depot by using a proxy, if you have configured a proxy password, it is stored in the configuration as plain text, which in some environments might be a security concern.

Workaround: Instead of configuring a password, you can pass the password every time you run a `Downland (-D)` and `Re-Download (-R)` command. For example, `./vmware-umds -D --proxy-username "<your_username>" --proxy-password "<your_password>" --proxy-port 80 --proxy-ip 1.1.1.1` .

Known Issues from Prior Releases

vSphere Cluster Services Issues

If all vSphere Cluster Service agent virtual machines in a cluster are down, vSphere DRS does not function in the cluster

If vSphere Cluster Service agent virtual machines fail to deploy or power on in a cluster, services such as vSphere DRS might be impacted.

Workaround: For more information on the issue and workarounds, see VMware knowledge base article 79892.

System virtual machines that support vSphere Cluster Services might impact cluster and datastore maintenance workflows

In vCenter Server 7.0 Update 1, vSphere Cluster Services adds a set of system virtual machines in every vSphere cluster to ensure the healthy operation of vSphere DRS. The system virtual machines deploy automatically with an implicit datastore selection logic. Depending on your cluster configuration, the system virtual machines might impact some of the cluster and datastore maintenance workflows.

Workaround: For more information on the impacted workflows and possible workarounds, see VMware knowledge base articles 79892 and 80483.

Installation, Upgrade, and Migration Issues

Upgrade to vSphere 7.0 Update 3c might require additional steps to force a full host-sync

The supported upgrade sequence for vSphere systems is first to upgrade vCenter Server and then ESXi. However, in certain environments with ESXi hosts of version 7.0 Update 2d and later, you need to update ESXi first to 7.0 Update 3c and then vCenter Server. Such an upgrade sequence requires additional steps to force a full host-sync.

Workaround: Log in to the appliance shell as a user with super administrative privileges (for example, `root`) and follow these steps:

1. Stop the vpxd service.
2. Run the command `/opt/vmware/vpostgres/current/bin/psql -U postgres -d VCDB -c "update VPX_HOST_SYNC_GEN set master_gen=0 where host_id in (select id from VPX_HOST where product_version like '7.0.3%')"`.
3. Start the vpxd service.

Patching vCenter to version 7.0 Update 3q might fail due to unsupported TLS ciphers in the Envoy proxy configuration

During the update of a vCenter instance to version 7.0 Update 3q, some services might fail to start due to custom configuration of the TLS cipher suites in the file `/etc/vmware-rhttpproxy/config.xml` . As a result, in the vSphere Client you see a warning such as `An error occurred while starting service 'vpxd-svcs'` and the process fails. If you use the Virtual Appliance Management Interface, you see an error such as `Installation Failed - Exception occurred in postInstallHook.`

Workaround: See KB 369485 for steps how to reset the TLS ciphers to their defaults and retry the vCenter update.

Hot-patched ESXi hosts with both i40en and i40enu Intel network drivers installed might fail to configure vSphere High Availability after upgrade to vCenter Server 7.0 Update 3c

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3c adds an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. However, if you apply an ESXi hot patch that is released after vCenter Server 7.0 Update 3c and then upgrade your system to vCenter Server 7.0 Update 3c, the hot patch might not be listed in the precheck. As a result, you might not follow the proper steps to the upgrade and vSphere HA might fail to configure on such hosts.

Workaround: Upgrade the hot-patched ESXi hosts to version 7.0 Update 3c.

The vCenter Upgrade/Migration pre-checks fail with "Unexpected error 87"

The vCenter Server Upgrade/Migration pre-checks fail when the Security Token Service (STS) certificate does not contain a Subject Alternative Name (SAN) field. This situation occurs when you have replaced the vCenter 5.5 Single Sign-On certificate with a custom certificate that has no SAN field, and you attempt to upgrade to vCenter Server 7.0. The upgrade considers the STS certificate invalid and the pre-checks prevent the upgrade process from continuing.

Workaround: Replace the STS certificate with a valid certificate that contains a SAN field then proceed with the vCenter Server 7.0 Upgrade/Migration.

Problems upgrading to vSphere 7.0 with pre-existing CIM providers

After upgrade, previously installed 32-bit CIM providers stop working because ESXi requires 64-bit CIM providers. Customers may lose management API functions related to CIMPDK, NDDK (native DDK), HEXDK, VAIODK (IO filters), and see errors related to **uwglibc** dependency.

The syslog reports module missing, "32 bit shared libraries not loaded."

Workaround: There is no workaround. The fix is to download new 64-bit CIM providers from your vendor.

Patching to vCenter Server 7.0 Update 1 from earlier versions of vCenter Server 7.x is blocked when vCenter Server High Availability is enabled

Patching to vCenter Server 7.0 Update 1 from earlier versions of vCenter Server 7.x is blocked when vCenter Server High Availability is active.

Workaround: To patch your system to vCenter Server 7.0 Update 1 from earlier versions of vCenter Server 7.x, you must remove vCenter Server High Availability and delete the passive and witness nodes. After the upgrade, you must re-create your vCenter Server High Availability clusters.

Migration of a 6.7.x vCenter Server system to vCenter Server 7.x fails with an UnicodeEncodeError

If you select the option to import all data for configuration, inventory, tasks, events, and performance metrics, the migration of a 6.7.x vCenter Server system to vCenter Server 7.x might fail for any vCenter Server system that uses a non-English locale. At step 1 of stage 2 of the migration, in the vSphere Client, you see an error such as:

```
Error while exporting events and tasks data: …ERROR UnicodeEncodeError: Traceback (most recent call last):
```

Workaround: You can complete the migration operation by doing either:

- Select the default option **Configuration and Inventory** at the end of stage 1 of the migration. This option does not include tasks and events data.
- Clean the data in the events tables and run the migration again.

If a Windows vCenter Server system has a database password containing non-ASCII characters, pre-checks of the VMware Migration Assistant fail

If you try to migrate a 6.x vCenter Server system to vCenter Server 7.x by using the VMware Migration Assistant, and your system has a Windows OS, and uses an external database with a password containing non-ASCII characters, the operation fails. For example, Admin!23迁移. In the Migration Assistant console, you see the following error:

```
Error:Component com.vmware.vcdb failed with internal errorResolution:File Bugzilla PR to VPX/VPX/vcdb-upgrade
```

Workaround: None

During an update from vCenter Server 7.x to vCenter Server 7.0 Update 1, you get prompts to provide the vCenter Single Sign-On password

During an update from vCenter Server 7.x to vCenter Server 7.0 Update 1, you get prompts to provide vCenter Single Sign-On administrator password.

Workaround: If you run the update by using the vCenter Server Management Interface, you must provide the vCenter Single Sign-On administrator password.

If you run the update by using software-packages or CLI in an interactive manner, you must interactively provide the vCenter Single Sign-On administrator password.

If you run the update by using software-packages or CLI in a non-interactive manner, you must provide the vCenter Single Sign-On administrator password by an answer file in the format

```
{ "vmdir.password": "SSO Password of Administrator@<SSO-DOMAIN> user" }
```

Smart Card and RSA SecurID authentication might stop working after upgrading to vCenter Server 7.0

If you have configured vCenter Server for either Smart Card or RSA SecurID authentication, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057 before starting the vSphere 7.0 upgrade process. If you do not perform the workaround as described in the KB, you might see the following error messages and Smart Card or RSA SecurID authentication does not work.

"Smart card authentication may stop working. Smart card settings may not be preserved, and smart card authentication may stop working."

or

"RSA SecurID authentication may stop working. RSA SecurID settings may not be preserved, and RSA SecurID authentication may stop working."

Workaround: Before upgrading to vSphere 7.0, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057.

You might not be able to apply or remove NSX while you add ESXi hosts by using a vSphere Lifecycle Manager image to a cluster with enabled VMware vSphere High Availability

If you start an operation to apply or remove NSX while adding multiple ESXi hosts by using a vSphere Lifecycle Manager image to a vSphere HA-enabled cluster, the NSX-related operations might fail with an error in the vSphere Client such as:

```
vSphere HA agent on some of the hosts on cluster <cluster_name> is neither vSphere HA master agent nor connected to vSphere HA master agent. Verify that the HA configuration is correct.
```

The issue occurs because vSphere Lifecycle Manager configures vSphere HA for the ESXi hosts being added to the cluster one at a time. If you run an operation to apply or remove NSX while vSphere HA configure operations are still in progress, NSX operations might queue up between the vSphere HA configure operations for two different ESXi hosts. In such a case, the NSX operation fails with a cluster health check error, because the state of the cluster at that point does not match the expected state that all ESXi hosts have vSphere HA configured and running. The more ESXi hosts you add to a cluster at the same time, the more likely the issue is to occur.

Workaround: Deactivate and enable Sphere HA on the cluster. Proceed with the operations to apply or remove NSX.

After an upgrade of a vCenter Server 7.0 system, you cannot see the IP addresses of pods in the vSphere Pod Summary tab of the vSphere Client

If you upgrade your vCenter Server 7.0 system to a later version, you can no longer see the IP addresses of pods in the **vSphere Pod Summary** tab of the vSphere Client.

Workaround: Use the Kubernetes CLI Tools for vSphere to review details of pods:

1. As a prerequisite, copy the pod and namespace names.
   - In the vSphere Client, navigate to **Workload Management** > **Clusters.**
   - Copy the IP displayed in the **Control Plane Node IP Address** tab.
   - You can navigate to `https://<control_plane_node_IP_address>` and download the Kubernetes CLI Tools, `kubectl` and `kubectl-vsphere`.
     Alternatively, follow the steps in Download and Install the Kubernetes CLI Tools for vSphere.
2. Use the CLI plug-in for vSphere to review the pod details.
   a. Log in to the Supervisor cluster by using the command
      `kubectl vsphere login --server=https://<server_adress> --vsphere-username <your user account name> --insecure-skip-tls-verify`
   b. By using the names copied in step 1, run the commands for retrieving the pod details:
      `kubectl config use-context <namespace_name>`
      and
      `kubectl describe pod <pod_name> -n <namespace_name>`

As a result, you can see the IP address in an output similar to:

```
$ kubectl describe pod helloworld -n my-podvm-ns ...

Status: Running

IP: 10.0.0.10

IPs:
```

`IP: 10.0.0.10 ...`

Upgrading a vCenter Server with an external Platform Services Controller from 6.7u3 to 7.0 fails with VMAFD error

When you upgrade a vCenter Server deployment using an external Platform Services Controller, you converge the Platform Services Controller into a vCenter Server appliance. If the upgrade fails with the error `install.vmafd.vmdir_vdcpromo_error_21` , the VMAFD firstboot process has failed. The VMAFD firstboot process copies the VMware Directory Service Database (data.mdb) from the source Platform Services Controller and replication partner vCenter Server appliance.

Workaround: Deactivate TCP Segmentation Offload (TSO) and Generic Segmentation Offload (GSO) on the Ethernet adapter of the source Platform Services Controller or replication partner vCenter Server appliance before upgrading a vCenter Server with an external Platform Services Controller. See Knowledge Base article: https://kb.vmware.com/s/article/74678

vCenter Server system upgrades fail in the pre-check stage

Upgrades of your vCenter Server system might fail in the pre-check stage due to a limit in the authorization (Authz) connections. In the `/var/log/vmware/vpxd-svcs/vpxd-svcs*.log` file you see entries such as:

`Session count for user [after add]: <DOMAIN-NAME>\machine-xxxx is 200Session limit reached for user: <DOMAIN-NAME>\machine-xxxx with 200 sessions.`

You might also see delayed response from the vSphere Client to load the inventory.

Workaround: Restart vmware-vpxd-svcs in your vCenter Server system by using the command `service-control --restart vmware-vpxd-svcs` . Use the command only when no other activity runs in the vCenter Server system to avoid any interruptions to the workflow. For more information, see VMware knowledge base article 81953.

Upgrading vCenter Server using the CLI incorrectly preserves the Transport Security Layer (TLS) configuration for the vSphere Authentication Proxy service

If the vSphere Authentication Proxy service (`vmcam`) is configured to use a particular TLS protocol other than the default TLS 1.2 protocol, this configuration is preserved during the CLI upgrade process. By default, vSphere supports the TLS 1.2 encryption protocol. If you must use the TLS 1.0 and TLS 1.1 protocols to support products or services that do not support TLS 1.2, use the TLS Configurator Utility to enable or deactivate different TLS protocol versions.

Workaround: Use the TLS Configurator Utility to configure the `vmcam` port. To learn how to manage TLS protocol configuration and use the TLS Configurator Utility, see the *VMware Security* documentation.

You do not see a precheck error when patching to vCenter Server 7.0 Update 3c by using CLI

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3c adds an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. In some cases, if such hosts exist in your system, patching from an vCenter Server version earlier than 7.0 Update 3 to a version later than 7.0 Update 3 by using CLI might fail with the error `Installation failed. Retry to resume from the current state. Or please collect the VC support bundle..`

However, instead of this error, you must see the precheck error message.

Workaround: If you do not see the precheck error and patching your system to vCenter Server 7.0 Update 3c fails, make sure all ESXi hosts are upgraded to ESXi 7.0 Update 3c or higher, by using either a baseline created from an ISO or a single image, before upgrading vCenter Server. Do not use patch baselines based on the rollup bulletin. You can find additional debug log information at `/var/log/vmware/applmgmt` . For more details, see VMware knowledge base articles 87319 and 86447.

Smart card and RSA SecurID settings may not be preserved during vCenter Server upgrade

Authentication using RSA SecurID will not work after upgrading to vCenter Server 7.0. An error message will alert you to this issue when attempting to login using your RSA SecurID login.

Workaround: Reconfigure the smart card or RSA SecureID.

Upgrade to vSphere 7.0 Update 3c might require additional steps to force a full host-sync

The supported upgrade sequence for vSphere systems is first to upgrade vCenter Server and then ESXi. However, in certain environments with ESXi hosts of version 7.0 Update 2c and later, you need to update ESXi first to 7.0 Update 3c and then vCenter Server. Such an upgrade sequence requires additional steps to force a full host-sync.

Workaround: Log in to the appliance shell as a user with super administrative privileges (for example, `root`) and follow these steps:

1. Stop the vpxd service.
2. Run the command `/opt/vmware/vpostgres/current/bin/psql -U postgres -d VCDB -c "update VPX_HOST_SYNC_GEN set master_gen=0 where host_id in (select id from VPX_HOST where product_version like '7.0.3%')"`.
3. Start the vpxd service.

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with network error message

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with the error message `IP already exists in the network`. This prevents the migration process from configuring the network parameters on the new vCenter Server appliance. For more information, examine the log file: `/var/log/vmware/upgrade/UpgradeRunner.log`

Workaround:

1. Verify that all Windows Updates have been completed on the source vCenter Server for Windows instance, or deactivate automatic Windows Updates until after the migration finishes.
2. Retry the migration of vCenter Server for Windows to vCenter Server appliance 7.0.

Hot-patched ESXi hosts with both i40en and i40enu Intel network drivers installed might fail to configure vSphere High Availability after upgrade to vCenter Server 7.0 Update 3c

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3c adds an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. However, if you apply an ESXi hot patch that is released after vCenter Server 7.0 Update 3c and then upgrade your system to vCenter Server 7.0 Update 3c, the hot patch might not be listed in the precheck. As a result, you might not follow the proper steps to the upgrade and vSphere HA might fail to configure on such hosts.

Workaround: Upgrade the hot-patched ESXi hosts to version 7.0 Update 3c.

When you configure the number of virtual functions for an SR-IOV device by using the max_vfs module parameter, the changes might not take effect

In vSphere 7.0, you can configure the number of virtual functions for an SR-IOV device by using the Virtual Infrastructure Management (VIM) API, for example, through the vSphere Client. The task does not require reboot of the ESXi host. After you use the VIM API configuration, if you try to configure the number of SR-IOV virtual functions by using the `max_vfs` module parameter, the changes might not take effect because they are overridden by the VIM API configuration.

Workaround: None. To configure the number of virtual functions for an SR-IOV device, use the same method every time. Use the VIM API or use the `max_vfs` module parameter and reboot the ESXi host.

Upgraded vCenter Server appliance instance does not retain all the secondary networks (NICs) from the source instance

During a major upgrade, if the source instance of the vCenter Server appliance is configured with multiple secondary networks other than the VCHA NIC, the target vCenter Server instance will not retain secondary networks other than the VCHA NIC. If the source instance is configured with multiple NICs that are part of VDS port groups, the NIC configuration will not be preserved during the upgrade. Configurations for vCenter Server appliance instances that are part of the standard port group will be preserved.

Workaround: None. Manually configure the secondary network in the target vCenter Server appliance instance.

After upgrading or migrating a vCenter Server with an external Platform Services Controller, users authenticating using Active Directory lose access to the newly upgraded vCenter Server instance

After upgrading or migrating a vCenter Server with an external Platform Services Controller, if the newly upgraded vCenter Server is not joined to an Active Directory domain, users authenticating using Active Directory will lose access to the vCenter Server instance.

Workaround: Verify that the new vCenter Server instance has been joined to an Active Directory domain. See Knowledge Base article: https://kb.vmware.com/s/article/2118543

Migrating a vCenter Server for Windows with an external Platform Services Controller using an Oracle database fails

If there are non-ASCII strings in the Oracle events and tasks table the migration can fail when exporting events and tasks data. The following error message is provided: UnicodeDecodeError

Workaround: None.

After an ESXi host upgrade, a Host Profile compliance check shows non-compliant status while host remediation tasks fail

The non-compliant status indicates an inconsistency between the profile and the host.

This inconsistency might occur because ESXi 7.0 does not allow duplicate claim rules, but the profile you use contains duplicate rules. For example, if you attempt to use the Host Profile that you extracted from the host before upgrading ESXi 6.5 or ESXi 6.7 to version 7.0 and the Host Profile contains any duplicate claim rules of system default rules, you might experience the problems.

Workaround:

1. Remove any duplicate claim rules of the system default rules from the Host Profile document.
2. Check the compliance status.
3. Remediate the host.
4. If the previous steps do not help, reboot the host.

Error message displays in the vCenter Server Management Interface

After installing or upgrading to vCenter Server 7.0, when you navigate to the Update panel within the vCenter Server Management Interface, the error message "Check the URL and try again" displays. The error message does not prevent you from using the functions within the Update panel, and you can view, stage, and install any available updates.

Workaround: None.

Patching witness or passive nodes of environments with VMware vCenter Server High Availability enabled might fail

In environments with vCenter Server High Availability enabled, patching a witness or passive node might fail with a message similar to:

```
RuntimeError: unidentifiable C++ exception.
```

Workaround: Deactivate vCenter Server High Availability. Apply patches to your vCenter Server system. Re-enable vCenter Server High Availability.

After patching your vCenter Server system to vCenter Server 7.0.0a, the TLS version of the VC Storage Clients might revert to the default

If you have a TLS configuration for the VC Storage Clients service different from the default TLS 1.2 only, the TLS version might revert to the default after patching your vCenter Server system to vCenter Server 7.0.0a.

Workaround: Use the TLS Configuration utility to enable or deactivate TLS versions on your vCenter Server system after the update.

After updating your system to vCenter Server 7.0.0b, you see systemd core dump in the /var/core folder

After updating your system to vCenter Server 7.0.0b from either vCenter Server 7.0.0a or vCenter Server 7.0, in the `/var/core` folder you see systemd core dump, such as `core.systemd-journal.393` and `core.systemd-udevd.405` . The core dump is harmless and can be removed.

Workaround: None

After updating your vCenter Server system to 7.0.0b, the vCenter Server version is not updated in the Direct Console User Interface (DCUI)

After updating your system to vCenter Server 7.0.0b from vCenter Server 7.0.0a or vCenter Server 7.0, you still see the previous vCenter Server version in the DCUI.

Workaround: After you complete the update, to refresh the vCenter Server version, in the appliance shell, run the command `/usr/lib/applmgmt/dcui/notify` .

Update Planner fails with error Configured repository is not accessible due to network connectivity or incorrect URL

If you use Update Planner, which is part of vSphere Lifecycle Manager used to facilitate vCenter Server updates, you might see the following error in the vSphere Client:

`Configured repository is not accessible due to network connectivity or incorrect URL. Verify the repository settings.`

The issue occurs when you use a custom local repository, such as `https:///uploads/dpe/` or a DBC path, to store the extracted . If the custom repository for URL-based patching has an authentication policy, Update Planner might not be able to fetch the list of available updates.

Workaround: Configure the custom repository such that authentication is not needed to access the custom repository URL.

After upgrading to vCenter Server 7.0.0b, you see vSphere HA errors on vSphere Lifecycle Manager Image based clusters

After upgrading to vCenter Server 7.0.0b, on vSphere Lifecycle Manager Image based clusters that are configured with vSphere HA, you might see error messages about the vSphere HA configuration after logging in for the first time to the environment. In the vSphere Client, you see messages such as:

`Cannot complete the configuration of the vSphere HA agent on the host.` or

`Applying HA VIBs on the cluster encountered a failure.`

The issue occurs because exports of the image depot might take long and cause a timeout of the task. In the`/storage/log/vmware/vmware-updatemgr/vum-server/vmware-vum-server.log` you see this message: `Export taking too long (Failure case)`

Workaround: This is a transient issue that resolves in 10 minutes after the vCenter Server is up and running. The issue does not affect any functionality. vSphere HA on the affected clusters operates as expected. All operations related to virtual machines, such as power on and migration, work across the vSphere HA-enabled clusters while this error recovery is still in progress.

You do not see a precheck error when patching to vCenter Server 7.0 Update 3d by using CLI

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3d and later add an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. In some cases, if such hosts exist in your system, patching from a vCenter Server version earlier than 7.0 Update 3 to a version later than 7.0 Update 3 by using CLI might fail with the error `Installation failed. Retry to resume from the current state. Or please collect the VC support bundle.` . However, instead of this error, you must see the precheck error message.

Workaround: If you do not see the precheck error and patching your system to vCenter Server 7.0 Update 3d fails, make sure all ESXi hosts are upgraded to ESXi 7.0 Update 3d, by using either a baseline created from an ISO or a single image, before upgrading vCenter Server. Do not use patch baselines based on the rollup bulletin. You can find additional debug log information at `/var/log/vmware/applmgmt` . For more details, see VMware knowledge base articles 87319 and 86447.

Security Features Issues

Encrypted virtual machine fails to power on when HA-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled HA on the Trusted Cluster and one or more hosts in the cluster fails attestation, an encrypted virtual machine cannot power on.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Encrypted virtual machine fails to power on when DRS-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled DRS on the Trusted Cluster and one or more hosts in the cluster fails attestation, DRS might try to power on an encrypted virtual machine on an unattested host in the cluster. This operation puts the virtual machine in a locked state.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Migrating or cloning encrypted virtual machines across vCenter Server instances fails when attempting to do so using the vSphere Client

If you try to migrate or clone an encrypted virtual machine across vCenter Server instances using the vSphere Client, the operation fails with the following error message: "The operation is not allowed in the current state."

Workaround: You must use the vSphere APIs to migrate or clone encrypted virtual machines across vCenter Server instances.

Networking Issues

PR3304411: After batch cloning and customizing Windows virtual machines, the VMs network might not be configured

When cloning Windows VMs in bulk, a MAC address conflict might occur, causing vCenter to reassign new MAC addresses to the VMs. As a result, the guest customization process fails to configure properly the VMs network because it cannot match the original MAC address to the corresponding network card.

This issue is resolved in this release.

When you use the VMware Remote Console, the envoy service might intermittently fail

An issue with the envoy service specific to the VMware Remote Console might lead to intermittent failures of the service. As a result, the vCenter Server Management Interface or vCenter Server APIs might also become unavailable.

Workaround: Use the vSphere Client as an alternative to the VMware Remote Console.

Reduced throughput in networking performance on Intel 82599/X540/X550 NICs

The new queue-pair feature added to ixgben driver to improve networking performance on Intel 82599EB/X540/X550 series NICs might reduce throughput under some workloads in vSphere 7.0 as compared to vSphere 6.7.

Workaround: To achieve the same networking performance as vSphere 6.7, you can deactivate the queue-pair with a module parameter. To deactivate the queue-pair, run the command:

```
# esxcli system module parameters set -p "QPair=0,0,0,0..." -m ixgben
```

After running the command, reboot.

If you try to deactivate vSphere with Tanzu on a vSphere cluster, the operation stops with an error

If some virtual machines outside of a Supervisor Cluster reside on any of the NSX segment port groups on the cluster, the cleanup script cannot delete such ports and deactivate vSphere with Tanzu on the cluster. In the vSphere Client, you see the error `Cleanup requests to NSX Manager failed` and the operation stops at `Removing` status. In the `/var/log/vmware/wcp/wcpsvc.log` file, you see an error message such as

```
Segment path=[...] has x VMs or VIFs attached. Disconnect all VMs and VIFs before deleting a segment.
```

Workaround: Delete the virtual machines indicated in the `/var/log/vmware/wcp/wcpsvc.log` file from the segment. Wait for the operation to restore.

After upgrading to NSX 6.4.7, when a static IPv6 address is assigned to workload VMs on an IPv6 network, the VMs are unable to ping the IPv6 gateway interface of the edge

This issue occurs after upgrading the vSphere Distributed Switches from 6.x to 7.0.

Workaround 1:

Select the VDS where all the hosts are connected, go to the **Edit** setting, and under **Multicast** option switch to basic.

Workaround 2:

Add the following rules on the edge firewall:

Ping allow rule.

Multicast Listener Discover (MLD) allow rule, which are icmp6, type 130 (v1) and type 143 (v2).

High throughput virtual machines may experience degradation in network performance when Network I/O Control (NetIOC) is enabled

Virtual machines requiring high network throughput can experience throughput degradation when upgrading from vSphere 6.7 to vSphere 7.0 with NetIOC enabled.

Workaround: Adjust the `ethernetx.ctxPerDev` setting to enable multiple worlds.

IPv6 traffic fails to pass through VMkernel ports using IPsec

When you migrate VMkernel ports from one port group to another, IPv6 traffic does not pass through VMkernel ports using IPsec.

Workaround: Remove the IPsec security association (SA) from the affected server, and then reapply the SA. To learn how to set and remove an IPsec SA, see the *vSphere Security* documentation.

Higher ESX network performance with a portion of CPU usage increase

ESX network performance may increase with a portion of CPU usage.

Workaround: Remove and add the network interface with only 1 rx dispatch queue. For example:

```
esxcli network ip interface remove --interface-name=vmk1
```

```
esxcli network ip interface add --interface-name=vmk1 --num-rxqueue=1
```

VM might lose Ethernet traffic after hot-add, hot-remove or storage vMotion

A VM might stop receiving Ethernet traffic after a hot-add, hot-remove or storage vMotion. This issue affects VMs where the uplink of the VNIC has SR-IOV enabled. PVRDMA virtual NIC exhibits this issue when the uplink of the virtual network is a Mellanox RDMA capable NIC and RDMA namespaces are configured.

Workaround: You can hot-remove and hot-add the affected Ethernet NICs of the VM to restore traffic. On Linux guest operating systems, restarting the network might also resolve the issue. If these workarounds have no effect, you can reboot the VM to restore network connectivity.

Change of IP address for a VCSA deployed with static IP address requires that you create the DNS records in advance

With the introduction of the DDNS, the DNS record update only works for VCSA deployed with DHCP configured networking. While changing the IP address of the vCenter server via VAMI, the following error is displayed:

The specified IP address does not resolve to the specified hostname.

Workaround: There are two possible workarounds.

1. Create an additional DNS entry with the same FQDN and desired IP address. Log in to the VAMI and follow the steps to change the IP address.
2. Log in to the VCSA using ssh. Execute the following script:
   `./opt/vmware/share/vami/vami_config_net`
   Use option 6 to change the IP adddress of eth0. Once changed, execute the following script:
   `./opt/likewise/bin/lw-update-dns`
   Restart all the services on the VCSA to update the IP information on the DNS server.

It may take several seconds for the NSX Distributed Virtual Port Group (NSX DVPG) to be removed after deleting the corresponding logical switch in NSX Manager.

As the number of logical switches increases, it may take more time for the NSX DVPG in vCenter Server to be removed after deleting the corresponding logical switch in NSX Manager. In an environment with 12000 logical switches, it takes approximately 10 seconds for an NSX DVPG to be deleted from vCenter Server.

Workaround: None.

Hostd runs out of memory and fails if a large number of NSX Distributed Virtual port groups are created.

In vSphere 7.0, NSX Distributed Virtual port groups consume significantly larger amounts of memory than opaque networks. For this reason, NSX Distributed Virtual port groups can not support the same scale as an opaque network given the same amount of memory.

Workaround:To support the use of NSX Distributed Virtual port groups, increase the amount of memory in your ESXi hosts. If you verify that your system has adequate memory to support your VMs, you can directly increase the memory of `hostd` using the following command.

```
localcli --plugin-dir /usr/lib/vmware/esxcli/int/ sched group setmemconfig --group-path
host/vim/vmvisor/hostd --units mb --min 2048 --max 2048
```

Note that this will cause `hostd` to use memory normally reserved for your environment's VMs. This may have the affect of reducing the number of VMs your ESXi host can support.

DRS may incorrectly launch vMotion if the network reservation is configured on a VM

If the network reservation is configured on a VM, it is expected that DRS only migrates the VM to a host that meets the specified requirements. In a cluster with NSX transport nodes, if some of the transport nodes join the transport zone by NSX-T Virtual Distributed Switch (N-VDS), and others by vSphere Distributed Switch (VDS) 7.0, DRS may incorrectly launch vMotion. You might encounter this issue when:

- The VM connects to an NSX logical switch configured with a network reservation.
- Some transport nodes join transport zone using N-VDS, and others by VDS 7.0, or, transport nodes join the transport zone through different VDS 7.0 instances.

Workaround: Make all transport nodes join the transport zone by N-VDS or the same VDS 7.0 instance.

When adding a VMkernel NIC (vmknic) to an NSX portgroup, vCenter Server reports the error "Connecting VMKernel adapter to a NSX Portgroup on a Stateless host is not a supported operation. Please use Distributed Port Group instead."

- For stateless ESXi on Distributed Virtual Switch (VDS), the vmknic on a NSX port group is blocked. You must instead use a Distributed Port Group.
- For stateful ESXi on VDS, vmknic on NSX port group is supported, but vSAN may have an issue if it is using vmknic on a NSX port group.

Workaround: Use a Distributed Port Group on the same VDS.

Enabling SRIOV from vCenter for QLogic 4x10GE QL41164HFCU CNA might fail

If you navigate to the **Edit Settings** dialog for physical network adapters and attempt to enable SR-IOV, the operation might fail when using QLogic 4x10GE QL41164HFCU CNA. Attempting to enable SR-IOV might lead to a network outage of the ESXi host.

Workaround: Use the following command on the ESXi host to enable SRIOV:

```
esxcfg-module
```

Storage Issues

VMFS datastores are not mounted automatically after disk hot remove and hot insert on HPE Gen10 servers with SmartPQI controllers

When SATA disks on HPE Gen10 servers with SmartPQI controllers without expanders are hot removed and hot inserted back to a different disk bay of the same machine, or when multiple disks are hot removed and hot inserted back in a different order, sometimes a new local name is assigned to the disk. The VMFS datastore on that disk appears as a snapshot and will not be mounted back automatically because the device name has changed.

Workaround: None. SmartPQI controller does not support unordered hot remove and hot insert operations.

ESXi might terminate I/O to NVMeOF devices due to errors on all active paths

Occasionally, all active paths to NVMeOF device register I/O errors due to link issues or controller state. If the status of one of the paths changes to Dead, the High Performance Plug-in (HPP) might not select another path if it shows high volume of errors. As a result, the I/O fails.

Workaround: Deactivate the configuration option **/Misc/HppManageDegradedPaths** to unblock the I/O.

VOMA check on NVMe based VMFS datastores fails with error

VOMA check is not supported for NVMe based VMFS datastores and will fail with the error:

```
ERROR: Failed to reserve device. Function not implemented
```

Example:

```
# voma -m vmfs -f check -d /vmfs/devices/disks/: <partition#>
Running VMFS Checker version 2.1 in check mode
Initializing LVM metadata, Basic Checks will be done

Checking for filesystem activity
Performing filesystem liveness check..|Scanning for VMFS-6 host activity (4096 bytes/HB, 1024 HBs).
ERROR: Failed to reserve device. Function not implemented
Aborting VMFS volume check
VOMA failed to check device : General Error
```

Workaround: None. If you need to analyse VMFS metadata, collect it using the `-l` option, and pass to VMware customer support. The command for collecting the dump is:

```
voma -l -f dump -d /vmfs/devices/disks/:<partition#>
```

Using the VM reconfigure API to attach an encrypted First Class Disk to an encrypted virtual machine might fail with error

If an FCD and a VM are encrypted with different crypto keys, your attempts to attach the encrypted FCD to the encrypted VM using the `VM reconfigure API` might fail with the error message:

```
Cannot decrypt disk because key or password is incorrect.
```

Workaround: Use the `attachDisk API` rather than the `VM reconfigure API` to attach an encrypted FCD to an encrypted VM.

ESXi host might get in non responding state if a non-head extent of its spanned VMFS datastore enters the Permanent Device Loss (PDL) state

This problem does not occur when a non-head extent of the spanned VMFS datastore fails along with the head extent. In this case, the entire datastore becomes inaccessible and no longer allows I/Os.

In contrast, when only a non-head extent fails, but the head extent remains accessible, the datastore heartbeat appears to be normal. And the I/Os between the host and the datastore continue. However, any I/Os that depend on the failed non-head extent start failing as well. Other I/O transactions might accumulate while waiting for the failing I/Os to resolve, and cause the host to enter the non responding state.

Workaround: Fix the PDL condition of the non-head extent to resolve this issue.

After recovering from APD or PDL conditions, VMFS datastore with enabled support for clustered virtual disks might remain inaccessible

You can encounter this problem only on datastores where the clustered virtual disk support is enabled. When the datastore recovers from an All Paths Down (APD) or Permanent Device Loss (PDL) condition, it remains inaccessible. The VMkernel log might show multiple `SCSI3 reservation conflict` messages similar to the following:

```
2020-02-18T07:41:10.273Z cpu22:1001391219)ScsiDeviceIO: vm 1001391219:
SCSIDeviceCmdCompleteCB:2972: Reservation conflict retries 544 for command 0x45ba814b8340
(op: 0x89) to device "naa.624a9370b97601e346f64ba900024d53"
```

The problem can occur because the ESXi host participating in the cluster loses SCSI reservations for the datastore and cannot always reacquire them automatically after the datastore recovers.

Workaround: Manually register the reservation using the following command:

```
vmkfstools -L registerkey /vmfs/devices/disks/<device name>
```

where the `<device name>` is the name of the device on which the datastore is created.

Virtual NVMe Controller is the default disk controller for Windows 10 guest operating systems

The Virtual NVMe Controller is the default disk controller for the following guest operating systems when using Hardware Version 15 or later:

Windows 10

Windows Server 2016

Windows Server 2019

Some features might not be available when using a Virtual NVMe Controller. For more information, see https://kb.vmware.com/s/article/2147714

Note: Some clients use the previous default of LSI Logic SAS. This includes ESXi host client and PowerCLI.

Workaround: If you need features not available on Virtual NVMe, switch to VMware Paravirtual SCSI (PVSCSI) or LSI Logic SAS. For information on using VMware Paravirtual SCSI (PVSCSI), see https://kb.vmware.com/s/article/1010398

After an ESXi host upgrade to vSphere 7.0, presence of duplicate core claim rules might cause unexpected behavior

Claim rules determine which multipathing plugin, such as NMP, HPP, and so on, owns paths to a particular storage device. ESXi 7.0 does not support duplicate claim rules. However, the ESXi 7.0 host does not alert you if you add duplicate rules to the existing claim rules inherited through an upgrade from a legacy release. As a result of using duplicate rules, storage devices might be claimed by unintended plugins, which can cause unexpected outcome.

Workaround: Do not use duplicate core claim rules. Before adding a new claim rule, delete any existing matching claim rule.

A CNS query with the compliance status filter set might take unusually long time to complete

The CNS QueryVolume API enables you to obtain information about the CNS volumes, such as volume health and compliance status. When you check the compliance status of individual volumes, the results are obtained quickly. However, when you invoke the CNS QueryVolume API to check the compliance status of multiple volumes, several tens or hundreds, the query might perform slowly.

Workaround: Avoid using bulk queries. When you need to get compliance status, query one volume at a time or limit the number of volumes in the query API to 20 or fewer. While using the query, avoid running other CNS operations to get the best performance.

New Deleted CNS volumes might temporarily appear as existing in the CNS UI

After you delete an FCD disk that backs a CNS volume, the volume might still show up as existing in the CNS UI. However, your attempts to delete the volume fail. You might see an error message similar to the following:

```
The object or item referred to could not be found.
```

Workaround: The next full synchronization will resolve the inconsistency and correctly update the CNS UI.

New Under certain circumstances, while a CNS operation fails, the task status appears as successful in the vSphere Client

This might occur when, for example, you use an incompliant storage policy to create a CNS volume. The operation fails, while the vSphere Client shows the task status as successful.

Workaround: The successful task status in the vSphere Client does not guarantee that the CNS operation succeeded. To make sure the operation succeeded, verify its results.

New Unsuccessful delete operation for a CNS persistent volume might leave the volume undeleted on the vSphere datastore

This issue might occur when the CNS Delete API attempts to delete a persistent volume that is still attached to a pod. For example, when you delete the Kubernetes namespace where the pod runs. As a result, the volume gets cleared from CNS and the CNS query operation does not return the volume. However, the volume continues to reside on the datastore and cannot be deleted through the repeated CNS Delete API operations.

Workaround: None.

vCenter Server and vSphere Client Issues

PR 3262556: vCenter upgrade fails with "VP last sync time not updated after waiting for 5 minutes after vCenter update"

In rare cases, during a vCenter upgrade, a race condition between vSphere API for Storage Awareness (VASA) providers might cause the upgrade to fail. In the `pod-service.log` file, you see an error such as `vSAN VP last sync time not updated after waiting for 5 minutes after vCenter update.`

This issue is resolved in this release. The fix prevents the race condition.

You do not see the VLAN ID in the port properties page of a VMkernel network adapter in the vSphere Client

In the vSphere Client, when you follow the path **Host > Add Networking**, after you select a VMkernel network adapter and an existing standard switch, in the **Port properties** page you might not see the VLAD ID. The issue occurs because the VLAN ID component is part of the `network-ui` module, which is lazy loaded and needs a trigger to refresh.

Workaround: Go to **Host > Configure > Networking > Virtual Switches** to trigger the loading of the `network ui` module and the VLAD ID appears.

Vendor providers go offline after a PNID change

When you change the vCenter IP address (PNID change), the registered vendor providers go offline.

Workaround: Re-register the vendor providers.

Cross vCenter migration of a virtual machine fails with an error

When you use cross vCenter vMotion to move a VM's storage and host to a different vCenter server instance, you might receive the error `The operation is not allowed in the current state.`

This error appears in the UI wizard after the Host Selection step and before the Datastore Selection step, in cases where the VM has an assigned storage policy containing host-based rules such as encryption or any other IO filter rule.

Workaround: Assign the VM and its disks to a storage policy without host-based rules. You might need to decrypt the VM if the source VM is encrypted. Then retry the cross vCenter vMotion action.

Storage Sensors information in Hardware Health tab shows incorrect values on vCenter UI, host UI, and MOB

When you navigate to **Host > Monitor > Hardware Health > Storage Sensors** on vCenter UI, the storage information displays either incorrect or unknown values. The same issue is observed on the host UI and the MOB path `"runtime.hardwareStatusInfo.storageStatusInfo"` as well.

Workaround: None.

vSphere UI host advanced settings shows the current product locker location as empty with an empty default

vSphere UI host advanced settings shows the current product locker location as empty with an empty default. This is inconsistent as the actual product location `symlink` is created and valid. This causes confusion to the user. The default cannot be corrected from UI.

Workaround: User can use the esxcli command on the host to correct the current product locker location default as below.

1. Remove the existing Product Locker Location setting with: "`esxcli system settings advanced remove -o ProductLockerLocation`"

2. Re-add the Product Locker Location setting with the appropriate default:

2.a. If the ESXi is a full installation, the default value is "`/locker/packages/vmtoolsRepo`" `export PRODUCT_LOCKER_DEFAULT="/locker/packages/vmtoolsRepo"`

2.b. If the ESXi is a PXEboot configuration such as autodeploy, the default value is: "`/vmtoolsRepo`" `export PRODUCT_LOCKER_DEFAULT="/vmtoolsRepo"`

Run the following command to automatically figure out the location: `export PRODUCT_LOCKER_DEFAULT=`readlink /productLocker``

Add the setting: `esxcli system settings advanced add -d "Path to VMware Tools repository" -o ProductLockerLocation -t string -s $PRODUCT_LOCKER_DEFAULT`

You can combine all the above steps in step 2 by issuing the single command:

```
esxcli system settings advanced add -d "Path to VMware Tools repository" -o
ProductLockerLocation -t string -s `readlink /productLocker`
```

Skyline Health page displays garbage characters

In the vSphere Client, when you navigate to vCenter Server or select an ESXi host in the vSphere Client navigator and click Monitor > Skyline Health, the page displays garbage characters in the following locales: Korean, Japanese, German and French.

Workaround: Switch to English locale.

Virtual Machine Management Issues

You cannot add or modify an existing network adapter on a virtual machine

If you try to add or modify an existing network adapter on a virtual machine, the Reconfigure Virtual Machine task might fail with an error such as `Cannot complete operation due to concurrent modification by another operation` in the vSphere Client. In the`/var/log/hostd.log` file of the ESXi host where the virtual machine runs, you see logs such as:

```
2020-07-28T07:47:31.621Z verbose hostd[2102259] [Originator@6876 sub=Vigor.Vmsvc.vm:/
vmfs/volumes/vsan:526bc94351cf8f42-41153841cab2f9d9/bad71f5f-d85e-a276-4cf6-246e965d7154/
interop_l2vpn_vmotion_VM_1.vmx] NIC: connection control message: Failed to connect virtual
device 'ethernet0'.
```

In the `vpxa.log` file, you see entries similar to: `2020-07-28T07:47:31.941Z info vpxa[2101759] [Originator@6876 sub=Default opID=opId-59f15-19829-91-01-ed] [VpxLRO] -- ERROR task-138 -- vm-13 -- vim.VirtualMachine.reconfigure: vim.fault.GenericVmConfigFault:`

Workaround: For each ESXi host in your cluster do the following:

1. Connect to the ESXi host by using SSH and run the command
   `esxcli system module parameters set -a -p dvfiltersMaxFilters=8192 -m dvfilter`
2. Put the ESXi host in Maintenance Mode.
3. Reboot the ESXi host.

For more information, see VMware knowledge base article 80399.

ESXi 6.5 hosts with AMD Opteron Generation 3 (Greyhound) processors cannot join Enhanced vMotion Compatibility (EVC) AMD REV E or AMD REV F clusters on a vCenter Server 7.0 Update 1 system

In vCenter Server 7.0 Update 1, vSphere cluster services, such as vSphere DRS and vSphere HA, run on ESX agent virtual machines to make the services functionally independent of vCenter Server. However, the CPU baseline for AMD processors of the ESX agent virtual machines have POPCNT SSE4A instructions, which prevents ESXi 6.5 hosts with AMD Opteron Generation 3 (Greyhound) processors to enable EVC mode AMD REV E and AMD REV F on a vCenter Server 7.0 Update 1 system.

Workaround: None

The postcustomization section of the customization script runs before the guest customization

When you run the guest customization script for a Linux guest operating system, the `precustomization` section of the customization script that is defined in the customization specification runs before the guest customization and the `postcustomization` section runs after that. If you enable Cloud-Init in the guest operating system of a virtual machine, the `postcustomization` section runs before the customization due to a known issue in Cloud-Init.

Workaround: Deactivate Cloud-Init and use the standard guest customization.

Group migration operations in vSphere vMotion, Storage vMotion, and vMotion without shared storage fail with error

When you perform group migration operations on VMs with multiple disks and multi-level snapshots, the operations might fail with the error `com.vmware.vc.GenericVmConfigFault Failed waiting for data. Error 195887167. Connection closed by remote host, possibly due to timeout.`

Workaround: Retry the migration operation on the failed VMs one at a time.

Deploying an OVF or OVA template from a URL fails with a 403 Forbidden error

The URLs that contain an HTTP query parameter are not supported. For example, `http://webaddress.com?file=abc.ovf` or the Amazon pre-signed S3 URLs.

Workaround: Download the files and deploy them from your local file system.

Importing or deploying local OVF files containing non-ASCII characters in their name might fail with an error

When you import local `.ovf` files containing non-ASCII characters in their name, you might receive `400 Bad Request Error` . When you use such `.ovf` files to deploy a virtual machine in the vSphere Client, the deployment process stops at 0%. As a result, you might receive `400 Bad Request Error` or `500 Internal Server Error` .

Workaround:

1. Remove the non-ASCII characters from the `.ovf` and `.vmdk` file names.
   - To edit the `.ovf` file, open it with a text editor.
   - Search the non-ASCII `.vmdk` file name and change it to ASCII.
2. Import or deploy the saved files again.

New The third level of nested objects in a virtual machine folder is not visible

Perform the following steps:

1. Navigate to a data center and create a virtual machine folder.
2. In the virtual machine folder, create a nested virtual machine folder.
3. In the second folder, create another nested virtual machine, virtual machine folder, vApp, or VM Template.

As a result, from the VMs and Templates inventory tree you cannot see the objects in the third nested folder.

Workaround: To see the objects in the third nested folder, navigate to the second nested folder and select the VMs tab.

vSAN file services operations fail on vSphere Lifecycle Manager-enabled clusters

During a change in the state of an ESXi host, vSAN file services operations might fail on vSphere Lifecycle Manager-enabled clusters due to a race condition with the vSphere ESX Agent Manager (EAM). The problem happens during upgrades and operations, such as power on or power off, booting, or when the host exits maintenance or standby mode. The race condition occurs when an endpoint has been unavailable before the change of state of the ESXi host. In such cases, the EAM starts a remediation process that cannot be resolved and fails operations from other services, such as the vSAN file services.

Workaround: Restart the vSphere ESX Agent Manager.

vSphere HA and Fault Tolerance Issues

VMs in a cluster might be orphaned after recovering from storage inaccessibility such as a cluster wide APD

Some VMs might be in orphaned state after cluster wide APD recovers, even if HA and VMCP are enabled on the cluster.

This issue might be encountered when the following conditions occur simultaneously:

- All hosts in the cluster experience APD and do not recover until VMCP timeout is reached.
- HA primary initiates failover due to APD on a host.
- Power on API during HA failover fails due to one of the following:
  - APD across the same host
  - Cascading APD across the entire cluster
  - Storage issues
  - Resource unavailability
- FDM unregistration and VCs steal VM logic might initiate during a window where FDM has not unregistered the failed VM and VC's host synchronization responds that multiple hosts are reporting the same VM. Both FDM and VC unregister the different registered copies of the same VM from different hosts, causing the VM to be orphaned.

Workaround: You must unregister and reregister the orphaned VMs manually within the cluster after the APD recovers.

If you do not manually reregister the orphaned VMs, HA attempts failover of the orphaned VMs, but it might take between 5 to 10 hours depending on when APD recovers.

The overall functionality of the cluster is not affected in these cases and HA will continue to protect the VMs. This is an anomaly in what gets displayed on VC for the duration of the problem.

vSphere Lifecycle Manager Issues

vSphere Lifecycle Manager and vSAN File Services cannot be simultaneously enabled on a vSAN cluster in vSphere 7.0 release

If vSphere Lifecycle Manager is enabled on a cluster, vSAN File Services cannot be enabled on the same cluster and vice versa. In order to enable vSphere Lifecycle Manager on a cluster, which has VSAN File Services enabled already, first deactivate vSAN File Services and retry the operation. Please note that if you transition to a cluster that is managed by a single image, vSphere Lifecycle Manager cannot be deactivated on that cluster.

Workaround: None.

You cannot edit the VMware vSphere Lifecycle Manager Update Download scheduled task

In the vSphere Client, when you navigate to a vCenter Server instance and select **Scheduled Tasks** under the **Configure** tab, if you select the **VMware vSphere Lifecycle Manager Update Download** task and click **Edit**, you cannot modify the existing settings.

Workaround: You can edit the **VMware vSphere Lifecycle Manager Update Download** task by following the steps in the topic Configure the vSphere Lifecycle Manager Automatic Download Task.

When a hardware support manager is unavailable, vSphere High Availability (HA) functionality is impacted

If hardware support manager is unavailable for a cluster that you manage with a single image, where a firmware and drivers addon is selected and vSphere HA is enabled, the vSphere HA functionality is impacted. You may experience the following errors.

- Configuring vSphere HA on a cluster fails.
- Cannot complete the configuration of the vSphere HA agent on a host: `Applying HA VIBs on the cluster encountered a failure.`
- Remediating vSphere HA fails: `A general system error occurred: Failed to get Effective Component map.`
- Disabling vSphere HA fails: Delete Solution task failed. `A general system error occurred: Cannot find hardware support package from depot or hardware support manager.`

Workaround:

- If the hardware support manager is temporarily unavailable, perform the following steps.

1. Reconnect the hardware support manager to vCenter Server.
2. Select a cluster from the Hosts and Cluster menu.
3. Select the Configure tab.
4. Under Services, click vSphere Availability.
5. Re-enable vSphere HA.

- If the hardware support manager is permanently unavailable, perform the following steps.

1. Remove the hardware support manager and the hardware support package from the image specification
2. Re-enable vSphere HA.
3. Select a cluster from the Hosts and Cluster menu.
4. Select the Updates tab.
5. Click Edit .
6. Remove the firmware and drivers addon and click Save.
7. Select the Configure tab.
8. Under Services, click vSphere Availability.
9. Re-enable vSphere HA.

I/OFilter is not removed from a cluster after a remediation process in vSphere Lifecycle Manager

Removing I/OFilter from a cluster by remediating the cluster in vSphere Lifecycle Manager, fails with the following error message: `iofilter XXX already exists` . The iofilter remains listed as installed.

Workaround:

1. Call IOFilter API `UninstallIoFilter_Task` from the vCenter Server managed object (IoFilterManager).
2. Remediate the cluster in vSphere Lifecycle Manager.
3. Call IOFilter API `ResolveInstallationErrorsOnCluster_Task` from the vCenter Server managed object (IoFilterManager) to update the database.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, disabling and re-enabling vSphere HA causes a vSphere HA error state

Disabling and re-enabling vSphere HA during remediation process of a cluster, may fail the remediation process due to vSphere HA health checks reporting that hosts don't have vSphere HA VIBs installed. You may see the following error message: `Setting desired image spec for cluster failed.`

Workaround: After the cluster remediation operation has finished, deactivate and re-enable vSphere HA for the cluster.

Checking for recommended images in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the recommendation generation task could take more than an hour to finish or may appear to hang. The completion time for the recommendation task depends on the number of devices configured on each host and the number of image candidates from the depot that vSphere Lifecycle Manager needs to process before obtaining a valid image to recommend.

Workaround: None.

Checking for hardware compatibility in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the validation report generation task could take up to 30 minutes to finish or may appear to hang. The completion time depends on the number of devices configured on each host and the number of hosts configured in the cluster.

Workaround: None

Incomplete error messages in non-English languages are displayed, when remediating a cluster in vSphere Lifecycle Manager

You can encounter incomplete error messages for localized languages in the vCenter Server user interface. The messages are displayed, after a cluster remediation process in vSphere Lifecycle Manager fails. For example, your can observe the following error message.

The error message in English language: `Virtual machine 'VMC on DELL EMC -FileServer' that runs on cluster 'Cluster-1' reported an issue which prevents entering maintenance mode: Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

The error message in French language: `La VM « VMC on DELL EMC -FileServer », située sur le cluster « {Cluster-1} », a signalé un problème empêchant le passage en mode de maintenance : Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

Workaround: None.

When you convert a cluster that uses baselines to a cluster that uses a single image, a warning is displayed that vSphere HA VIBs will be removed

Converting a vSphere HA enabled cluster that uses baselines to a cluster that uses a single image, may result a warning message displaying that `vmware-fdm` component will be removed.

Workaround: This message can be ignored. The conversion process installs the `vmware-fdm` component.

If vSphere Update Manager is configured to download patch updates from the Internet through a proxy server, after upgrade to vSphere 7.0 that converts Update Manager to vSphere Lifecycle Manager, downloading patches from VMware patch repository might fail

In earlier releases of vCenter Server you could configure independent proxy settings for vCenter Server and vSphere Update Manager. After an upgrade to vSphere 7.0, vSphere Update Manager service becomes part of the vSphere Lifecycle Manager service. For the vSphere Lifecycle Manager service, the proxy settings are configured from the vCenter Server appliance settings. If you had configured Update Manager to download patch updates from the Internet through a proxy server but the vCenter Server appliance had no proxy setting configuration, after a vCenter Server upgrade to version 7.0, the vSphere Lifecycle Manager fails to connect to the VMware depot and is unable to download patches or updates.

Workaround: Log in to the vCenter Server Appliance Management Interface, https://*vcenter-server-appliance-FQDN-or-IP-address*:5480, to configure proxy settings for the vCenter Server appliance and enable vSphere Lifecycle Manager to use proxy.

If you use a Java client to review remediation tasks, you cannot extract the results from the remediation operations

If you use a Java client to review remediation tasks, extracting the results might fail with a `ConstraintValidationException` error. The issue occurs when an ESXi host fails to enter maintenance mode during the remediation and gets a status SKIPPED, but at the same time wrongly gets an In Progress flag for the consecutive remediation operations. This causes the `ConstraintValidationException` error on the Java Clients and you cannot extract the result of the remediation operation.

Workaround: Fix the underlying issues that prevent ESXi hosts to enter Maintenance Mode and retry the remediation operation.

The general vSphere Lifecycle Manager depot and local depots in Remote Office and Branch Office (ROBO) deployments might not be in sync

ROBO clusters that have limited or no access to the Internet or limited connectivity to vCenter Server can download an image from a depot that is local for them instead of accessing the vSphere Lifecycle Manager depot in vCenter Server. However, vSphere Lifecycle Manager generates software recommendations in the form of pre-validated images only on a central level and a recommended image content might not be available at a depot override.

Workaround: If you decide to use a recommended image, make sure the content between depot overrides and the central depot are in sync.

Cluster remediation by using the vSphere Lifecycle Manager might fail on ESXi hosts with enabled lockdown mode

If a cluster has ESXi hosts with enabled lockdown mode, remediation operations by using the vSphere Lifecycle Manager might skip such hosts. In the log files, you see messages such as `Host scan task failed` and `com.vmware.vcIntegrity.lifecycle.EsxImage.UnknownError An unknown error occurred while performing the operation.`.

Workaround: Add the root user to the exception list for lockdown mode and retry the cluster remediation.

You cannot use an ESXi image with OEM content to create clusters by using vSphere Lifecycle Manager workflows after an update

When you update an ESXi image with OEM content, for example Dell ESXi 7.0 Update 2a to Dell ESXi 7.0 Update 3d, some reserved VIBs, such that are present in the VMware base image but overridden by async VIBs packaged by the OEM, might be deleted. The same issue might occur after updating your system by using a non-critical baseline and then update to a higher version by using an ESXi image with OEM content. For example, if you update to 7.0 Update 2 by using a non-critical baseline and then update to 7.0 Update 3 by using a Dell ESXi 7.0 Update 3 image, reserved VIBs might also be deleted. As a result, you cannot use ESXi hosts with the updated version to create a vSphere Lifecycle Manager cluster managed by a single image. The operation fails and in the backtrace, you see errors such as:

```
2021-11-24T09:42:49Z lifecycle: 2101166: HostSeeding:956 ERROR Extract depot failed:
('VMW_bootbank_bnxtroce_216.0.58.0-23vmw.703.0.0.18644231', 'Failed to add reserved
VIB VMW_bootbank_bnxtroce_216.0.58.0-23vmw.703.0.0.18644231: not found in the reserved
VIB cache storage')2021-11-24T09:42:50Z lifecycle: 2101166: imagemanagerctl:373 ERROR
Extract depot failed.021-11-24T09:42:50Z lifecycle: 2101166: imagemanagerctl:152 ERROR
[ReservedVibExtractError] ('VMW_bootbank_bnxtroce_216.0.58.0-23vmw.703.0.0.18644231',
'Failed to add reserved VIB VMW_bootbank_bnxtroce_216.0.58.0-23vmw.703.0.0.18644231: not
found in the reserved VIB cache storage')
```

Workaround: Use interactive or scripted upgrade instead of vSphere Lifecycle Manager workflows.

After you upgrade to vCenter Server 7.0.0b, in the vSphere Lifecycle Manager home view in the vSphere Client, you do not see the Show only rollup updates toggle button

In vCenter Server 7.0.0b, you can use the **Show only rollup updates** toggle button to filter and select patches that you want to include in a baseline when you use the vSphere Lifecycle Manager.

The button is available in the **Updates** tab on the **Lifecycle Manager** pane, **Menu** > **Lifecycle Manager**, which is the vSphere Lifecycle Manager home view in the vSphere Client. The button is also available in the **Select Patches Manually** page on the **Baselines** tab in the **Create Baseline** wizard, which opens when you select **New** > **Baseline**.

However, the **Show only rollup updates** toggle button might not be visible after you upgrade to vCenter Server 7.0.0b.

Workaround: After an upgrade to vCenter Server 7.0.0b, restart the vSphere Client. For more information, see Start, Stop, and Restart Services.

The Show only rollup updates toggle button is always turned on when you open a tab in the vSphere Lifecycle Manager home view in the vSphere Client

In vCenter Server 7.0.0b, you can use the **Show only rollup updates** toggle button to filter and select patches that you want to include in a baseline when you use the vSphere Lifecycle Manager.

The button is available in the **Updates** tab on the **Lifecycle Manager** pane, **Menu** > **Lifecycle Manager**, which is the vSphere Lifecycle Manager home view in the vSphere Client. The button is also available in the **Select Patches Manually** page on the **Baselines** tab in the **Create Baseline** wizard, which opens when you select **New** > **Baseline**.

However, the toggle button appears always turned on when you navigate to either of the **Updates** tab or the **Select Patches Manually** page. Even if you turn off the button when navigating away from the tab or page, it appears still turned on the next time you open them.

Workaround: None

When you use the Update Planner, in the vSphere Client you might see Unexpected error occurred while fetching the updates

When you use Update Planner, which is part of vSphere Lifecycle Manager, used to facilitate vCenter Server updates, you might see the following error in the vSphere Client:

```
Unexpected error occurred while fetching the updates
```

The issue occurs when you use a custom HTTPS port that prevents you from running interoperability reports by using the vSphere Client.

Workaround: Manually invoke the API. For more details, see the vSphere Automation API.

Miscellaneous Issues

When applying a host profile with version 6.5 to a ESXi host with version 7.0, the compliance check fails

Applying a host profile with version 6.5 to a ESXi host with version 7.0, results in Coredump file profile reported as not compliant with the host.

Workaround: There are two possible workarounds.

1. When you create a host profile with version 6.5, set an advanced configuration option VMkernel.Boot.autoCreateDumpFile to false on the ESXi host.
2. When you apply an existing host profile with version 6.5, add an advanced configuration option VMkernel.Boot.autoCreateDumpFile in the host profile, configure the option to a fixed policy, and set value to false.

Cannot migrate container volume due to insufficient space

The Migrate volume dialog in vSphere Client considers the current size of container volumes and the free space available on the target datastores. If the free space of a datastore is less than the volume size, then you cannot select the datastore for migration. vSphere preserves the storage policy as it migrates the volume, but the file size of the volume might change depending on the destination datastore type and its supported features. The vSphere Client might show the datastore has insufficient space to perform the migration, even though enough space is available.

Workaround: None

The Actions drop-down menu does not contain any items when your browser is set to language different from English

When your browser is set to language different from English and you click the **Switch to New View** button from the virtual machine **Summary** tab of the vSphere Client inventory, the **Actions** drop-down menu in the **Guest OS** panel does not contain any items.

Workaround: Select the **Actions** drop-down menu on the top of the virtual machine page.

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit minor throughput degradation when Dynamic Receive Side Scaling (DYN_RSS) or Generic RSS (GEN_RSS) feature is turned on

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit less than 5 percent throughput degradation when DYN_RSS and GEN_RSS feature is turned on, which is unlikely to impact normal workloads.

Workaround: You can deactivate DYN_RSS and GEN_RSS feature with the following commands:

```
# esxcli system module parameters set -m nmlx5_core -p "DYN_RSS=0 GEN_RSS=0"
# reboot
```

RDMA traffic between two VMs on the same host might fail in PVRDMA environment

In a vSphere 7.0 implementation of a PVRDMA environment, VMs pass traffic through the HCA for local communication if an HCA is present. However, loopback of RDMA traffic does not work on qedrntv driver. For instance, RDMA Queue Pairs running on VMs that are configured under same uplink port cannot communicate with each other.

In vSphere 6.7 and earlier, HCA was used for local RDMA traffic if SRQ was enabled. vSphere 7.0 uses HCA loopback with VMs using versions of PVRDMA that have SRQ enabled with a minimum of HW v14 using RoCE v2.

The current version of Marvell FastLinQ adapter firmware does not support loopback traffic between QPs of the same PF or port.

Workaround: Required support is being added in the out-of-box driver certified for vSphere 7.0. If you are using the inbox qedrntv driver, you must use a 3-host configuration and migrate VMs to the third host.

Unreliable Datagram traffic QP limitations in qedrntv driver

There are limitations with the Marvell FastLinQ qedrntv RoCE driver and Unreliable Datagram (UD) traffic. UD applications involving bulk traffic might fail with qedrntv driver. Additionally, UD QPs can only work with DMA Memory Regions (MR).

Physical MRs or FRMR are not supported. Applications attempting to use physical MR or FRMR along with UD QP fail to pass traffic when used with qedrntv driver. Known examples of such test applications are `ibv_ud_pingpong` and `ib_send_bw`.

Standard RoCE and RoCEv2 use cases in a VMware ESXi environment such as iSER, NVMe-oF (RoCE) and PVRDMA are not impacted by this issue. Use cases for UD traffic are limited and this issue impacts a small set of applications requiring bulk UD traffic.

Marvell FastLinQ hardware does not support RDMA UD traffic offload. In order to meet the VMware PVRDMA requirement to support GSI QP, a restricted software only implementation of UD QP support was added to the qedrntv driver. The goal of the implementation is to provide support for control path GSI communication and is not a complete implementation of UD QP supporting bulk traffic and advanced features.

Since UD support is implemented in software, the implementation might not keep up with heavy traffic and packets might be dropped. This can result in failures with bulk UD traffic.

Workaround: Bulk UD QP traffic is not supported with qedrntv driver and there is no workaround at this time. VMware ESXi RDMA (RoCE) use cases like iSER, NVMe, RDMA and PVRDMA are unaffected by this issue.

Servers equipped with QLogic 578xx NIC might fail when frequently connecting or disconnecting iSCSI LUNs

If you trigger QLogic 578xx NIC iSCSI connection or disconnection frequently in a short time, the server might fail due to an issue with the qfle3 driver. This is caused by a known defect in the device's firmware.

Workaround: None.

ESXi might fail during driver unload or controller disconnect operation in Broadcom NVMe over FC environment

In Broadcom NVMe over FC environment, ESXi might fail during driver unload or controller disconnect operation and display an error message such as: `@BlueScreen: #PF Exception 14 in world 2098707:vmknvmeGener IP 0x4200225021cc addr 0x19`

Workaround: None.

ESXi does not display OEM firmware version number of i350/X550 NICs on some Dell servers

The inbox ixgben driver only recognizes firmware data version or signature for i350/X550 NICs. On some Dell servers the OEM firmware version number is programmed into the OEM package version region, and the inbox ixgben driver does not read this information. Only the 8-digit firmware signature is displayed.

Workaround: To display the OEM firmware version number, install async ixgben driver version 1.7.15 or later.

X710 or XL710 NICs might fail in ESXi

When you initiate certain destructive operations to X710 or XL710 NICs, such as resetting the NIC or manipulating VMKernel's internal device tree, the NIC hardware might read data from non-packet memory.

Workaround: Do not reset the NIC or manipulate vmkernel internal device state.

NVMe-oF does not guarantee persistent VMHBA name after system reboot

NVMe-oF is a new feature in vSphere 7.0. If your server has a USB storage installation that uses vmhba30+ and also has NVMe over RDMA configuration, the VMHBA name might change after a system reboot. This is because the VMHBA name assignment for NVMe over RDMA is different from PCIe devices. ESXi does not guarantee persistence.

Workaround: None.

Backup fails for vCenter database size of 300 GB or greater

If the vCenter database size is 300 GB or greater, the file-based backup will fail with a timeout. The following error message is displayed: `Timeout! Failed to complete in 72000 seconds`

Workaround: None.

A restore of vCenter Server 7.0 which is upgraded from vCenter Server 6.x with External Platform Services Controller to vCenter Server 7.0 might fail

When you restore a vCenter Server 7.0 which is upgraded from 6.x with External Platform Services Controller to vCenter Server 7.0, the restore might fail and display the following error: `Failed to retrieve appliance storage list`

Workaround: During the first stage of the restore process, increase the storage level of the vCenter Server 7.0. For example if the vCenter Server 6.7 External Platform Services Controller setup storage type is small, select storage type large for the restore process.

Enabled SSL protocols configuration parameter is not configured during a host profile remediation process

`Enabled SSL protocols` configuration parameter is not configured during a host profile remediation and only the system default protocol `tlsv1.2` is enabled. This behavior is observed for a host profile with version 7.0 and earlier in a vCenter Server 7.0 environment.

Workaround: To enable TLSV 1.0 or TLSV 1.1 SSL protocols for SFCB, log in to an ESXi host by using SSH, and run the following ESXCLI command: `esxcli system wbem -P <protocol_name>`

Unable to configure Lockdown Mode settings by using Host Profiles

Lockdown Mode cannot be configured by using a security host profile and cannot be applied to multiple ESXi hosts at once. You must manually configure each host.

Workaround: In vCenter Server 7.0, you can configure Lockdown Mode and manage Lockdown Mode exception user list by using a security host profile.

When a host profile is applied to a cluster, Enhanced vMotion Compatibility (EVC) settings are missing from the ESXi hosts

Some settings in the VMware config file `/etc/vmware/config` are not managed by Host Profiles and are blocked, when the config file is modified. As a result, when the host profile is applied to a cluster, the EVC settings are lost, which causes loss of EVC functionalities. For example, unmasked CPUs can be exposed to workloads.

Workaround: Reconfigure the relevant EVC baseline on cluster to recover the EVC settings.

Using a host profile that defines a core dump partition in vCenter Server 7.0 results in an error

In vCenter Server 7.0, configuring and managing a core dump partition in a host profile is not available. Attempting to apply a host profile that defines a core dump partition, results in the following error: `No valid coredump partition found.`

Workaround: None. In vCenter Server 7.0., Host Profiles supports only file-based core dumps.

You cannot paste by right clicking in the vi editor

If you use the vi text editor on a vCenter Server Appliance instance, you cannot paste previously copied content by right clicking. Instead, the vi editor changes mode to Visual.

Workaround: From the vCenter Server Appliance shell, run the command`/usr/bin/sed -i.bak -E '2alet skip_defaults_vim=1' /etc/vimrc`.

HTTP requests from certain libraries to vSphere might be rejected

The HTTP reverse proxy in vSphere 7.0 enforces stricter standard compliance than in previous releases. This might expose pre-existing problems in some third-party libraries used by applications for SOAP calls to vSphere.

If you develop vSphere applications that use such libraries or include applications that rely on such libraries in your vSphere stack, you might experience connection issues when these libraries send HTTP requests to VMOMI. For example, HTTP requests issued from vijava libraries can take the following form:

```
POST /sdk HTTP/1.1
SOAPAction
Content-Type: text/xml; charset=utf-8
User-Agent: Java/1.8.0_221
```

The syntax in this example violates an HTTP protocol header field requirement that mandates a colon after SOAPAction. Hence, the request is rejected in flight.

Workaround: Developers leveraging noncompliant libraries in their applications can consider using a library that follows HTTP standards instead. For example, developers who use the vijava library can consider using the latest version of the yavijava library instead.

SNMP dynamic firewall ruleset is modified by Host Profiles during a remediation process

The SNMP firewall ruleset is a dynamic state, which is handled during runtime. When a host profile is applied, the configuration of the ruleset is managed simultaneously by Host Profiles and SNMP, which can modify the firewall settings unexpectedly.

Workaround: There are two possible workarounds.

- To allow the ruleset to manage itself dynamically, exclude the SNMP firewall ruleset option in the configuration of the host profile.
- To proceed with the double management of the ruleset, when needed, correct the firewall ruleset state.

You might see a dump file when using Broadcom driver lsi_msgpt3, lsi_msgpt35 and lsi_mr3

When using the lsi_msgpt3, lsi_msgpt35 and lsi_mr3 controllers, there is a potential risk to see dump file lsuv2-lsi-drivers-plugin-util-zdump. There is an issue when exiting the storelib used in this plugin utility. There is no impact on ESXi operations, you can ignore the dump file.

Workaround: You can safely ignore this message. You can remove the lsuv2-lsi-drivers-plugin with the following command:

```
esxcli software vib remove -n lsuv2-lsiv2-drivers-plugin
```

You might see reboot is not required after configuring SR-IOV of a PCI device in vCenter, but device configurations made by third party extensions might be lost and require reboot to be re-applied.

In ESXi 7.0, SR-IOV configuration is applied without a reboot and the device driver is reloaded. ESXi hosts might have third party extensions perform device configurations that need to run after the device driver is loaded during boot. A reboot is required for those third party extensions to re-apply the device configuration.

Workaround: You must reboot after configuring SR-IOV to apply third party device configurations.

You see black or grey zones in the background of a parent window in the Direct Console User Interface (DCUI) after a child window closes

In the DCUI, when you close a child window by pressing the ESC or Enter keys, or the **Cancel** or **OK** buttons, the parent window appearance might change. The background color changes to grey or black for some part of the parent window. However, all required information from the DCUI is properly displayed and all operations performed in the DCUI complete successfully.

Workaround: Wait for 1 minute without refreshing the current window in the DCUI or pressing any key.

Backup Issues

If you use the NFS and SMB protocols for file-based backup of vCenter Server, the backup fails after an update from vCenter Server 7.x to vCenter Server 7.0 Update 1

If you use the Network File System (NFS) and Server Message Block (SMB) protocols for file-based backup of vCenter Server, the backup fails after an update from an earlier version of vCenter Server 7.x to vCenter Server 7.0 Update 1. In the `applmgmt.log` , you see an error message such as `Failed to mount the remote storage` . The issue occurs because of Linux kernel updates that run during the patch process. The issue does not occur on fresh installations of vCenter Server 7.0 Update 1.

Workaround: Reboot the vCenter Server appliance after the update is complete.

Microsoft Active Directory Federation Services (ADFS) logins might fail after restoring a vCenter Server Appliance

If you manually add a certificate to the vCenter Server JRE truststore or modify the `/etc/hosts` file when setting up ADFS, the changes are not preserved after restoring and might cause ADFS logins to fail.

Workaround: Add the ADFS certificate to the vCenter Server JRE truststore after restoring your vCenter Server Appliance. For more information, see Import the Trusted Certificate of an External Identity Provider. Add the necessary host name mappings back to the `/etc/hosts` file after restoring your vCenter Server Appliance.

vSAN Issues

Higher than actual vSAN storage pool free space estimate might lead to unexpected storage shortages

The `freeSpace` parameter of a vSAN storage pool might not exclude disks with errors and display the unused space estimate as higher than the actual. As a result, you might see unexpected storage shortages. This issue only affects vSAN storage pools.

Workaround: Manually compute the storage capacity by disregarding the `freeSpace` value of disks with errors from the overall storage capacity provided by the `freeSpace` parameter of the storage pool.

Server Configuration Issues

You see a message Error retrieving when trying to view the status of Key Management Server (KMS) instances in the vSphere Client

In the vSphere Client, you might see a message `Error retrieving` for several minutes when trying to view Key Management Server (KMS) instances. The issue occurs when a KMS instance in a standard key provider loses connectivity. Until all network requests to the affected KMS time out, which takes around 4 minutes, you cannot see the status of any KMS instance in your system, only the error message for the key provider. After the timeout, you can see the status of all KMS instances.

Workaround: If you see the Error retrieving message, wait for 4 minutes.

Due to a default timeout setting of 2 minutes, log in to vCenter instances in Enhanced Linked Mode takes long when any of the vCenters is down

When you have a number of vCenter instances in Enhanced Linked Mode, if one of the instances is down for some reason, such as maintenance, log in to the other instances might take up to 2 minutes, which is the default timeout setting. Changing the timeout property that specifies the wait time for log in to linked vCenter instances is a complex task that requires manually editing the `LinkedVcGroup.login.timeout` property located in `vim-commons-vsphere.properties` . To simlify the task, starting with vCenter Server 7.0 Update 3l, the

setting `LinkedVcGroup.login.timeout=120000` moves from `vim-commons-vsphere.properties` to the `webclient.properties` file. Editing this option allows you to reduce the wait time so that if one of the vCenter logins is taking more time, it does not affect the log in time for other instances.

Workaround: Edit `/etc/vmware/vsphere-ui/webclient.properties` and change the value of `LinkedVcGroup.login.timeout` from `120000` to a smaller value in milliseconds, but consider that a value of `<= 0` is an infinite timeout.

VMware vCenter Server 7.0 Update 3w Release Notes

This document contains the following sections

- Introduction
- What's New
- Patches Contained in This Release
- Resolved Issues
- Known Issues from Prior Releases

Introduction

VMware vCenter Server 7.0 Update 3w | 29 SEP 2025 | ISO Build 24927011 Check for additions and updates to these release notes.

What's New

- This release resolves CVE-2025-41250. For more information on this vulnerability and its impact on Broadcom products, see VMSA-2025-0016.

Patches Contained in This Release

Patch for VMware vCenter 7.0 Update 3w

Download Filename	VMware-vCenter-Server-Appliance-7.0.3.02500-24927011-patch-FP.iso
Build	24927011
Download Size	6.23 GB
md5sum	0c9673c05cc9a92b80e4c4d3083f3979
sha256checksum	a1271853908a96d881e5e36fc70d2c1cc809b21fe3be38db29016588fdd9097c
PRs fixed	N/A
CVEs	CVE-2025-41250

Download and Installation

Log in to the Broadcom Support Portal to download this patch.

For download instructions for earlier releases, see Download Broadcom products and software.

For more information on using the vCenter Server shells, see VMware knowledge base article 2100508.

For more information on patching vCenter Server, see Patching the vCenter Server Appliance.

For more information on staging patches, see Stage Patches to vCenter Server Appliance.

For more information on installing patches, see Install vCenter Server Appliance Patches.

For more information on patching using the Appliance Management Interface, see Patching the vCenter Server by Using the Appliance Management Interface.

Resolved Issues

Security Issues

- This release resolves CVE-2025-41250. For more information on this vulnerability and its impact on Broadcom products, see VMSA-2025-0016.

Known Issues from Prior Releases

vSphere Cluster Services Issues

If all vSphere Cluster Service agent virtual machines in a cluster are down, vSphere DRS does not function in the cluster

If vSphere Cluster Service agent virtual machines fail to deploy or power on in a cluster, services such as vSphere DRS might be impacted.

Workaround: For more information on the issue and workarounds, see VMware knowledge base article 79892.

System virtual machines that support vSphere Cluster Services might impact cluster and datastore maintenance workflows

In vCenter Server 7.0 Update 1, vSphere Cluster Services adds a set of system virtual machines in every vSphere cluster to ensure the healthy operation of vSphere DRS. The system virtual machines deploy automatically with an implicit datastore selection logic. Depending on your cluster configuration, the system virtual machines might impact some of the cluster and datastore maintenance workflows.

Workaround: For more information on the impacted workflows and possible workarounds, see VMware knowledge base articles 79892 and 80483.

Installation, Upgrade, and Migration Issues

Upgrade to vSphere 7.0 Update 3c might require additional steps to force a full host-sync

The supported upgrade sequence for vSphere systems is first to upgrade vCenter Server and then ESXi. However, in certain environments with ESXi hosts of version 7.0 Update 2d and later, you need to update ESXi first to 7.0 Update 3c and then vCenter Server. Such an upgrade sequence requires additional steps to force a full host-sync.

Workaround: Log in to the appliance shell as a user with super administrative privileges (for example, `root`) and follow these steps:

1. Stop the vpxd service.
2. Run the command `/opt/vmware/vpostgres/current/bin/psql -U postgres -d VCDB -c "update VPX_HOST_SYNC_GEN set master_gen=0 where host_id in (select id from VPX_HOST where product_version like '7.0.3%')"`.
3. Start the vpxd service.

Patching vCenter to version 7.0 Update 3q might fail due to unsupported TLS ciphers in the Envoy proxy configuration

During the update of a vCenter instance to version 7.0 Update 3q, some services might fail to start due to custom configuration of the TLS cipher suites in the file `/etc/vmware-rhttpproxy/config.xml` . As a result, in the vSphere Client you see a warning such as `An error occurred while starting service 'vpxd-svcs'` and the process fails. If you use the Virtual Appliance Management Interface, you see an error such as `Installation Failed - Exception occurred in postInstallHook.`

Workaround: See KB 369485 for steps how to reset the TLS ciphers to their defaults and retry the vCenter update.

Hot-patched ESXi hosts with both i40en and i40enu Intel network drivers installed might fail to configure vSphere High Availability after upgrade to vCenter Server 7.0 Update 3c

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3c adds an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. However, if you apply an ESXi hot patch that is released after vCenter Server 7.0 Update 3c and then upgrade your system to vCenter Server 7.0 Update 3c, the hot patch might not be listed in the precheck. As a result, you might not follow the proper steps to the upgrade and vSphere HA might fail to configure on such hosts.

Workaround: Upgrade the hot-patched ESXi hosts to version 7.0 Update 3c.

The vCenter Upgrade/Migration pre-checks fail with "Unexpected error 87"

The vCenter Server Upgrade/Migration pre-checks fail when the Security Token Service (STS) certificate does not contain a Subject Alternative Name (SAN) field. This situation occurs when you have replaced the vCenter 5.5 Single Sign-On certificate with a custom certificate that has no SAN field, and you attempt to upgrade to vCenter Server 7.0. The upgrade considers the STS certificate invalid and the pre-checks prevent the upgrade process from continuing.

Workaround: Replace the STS certificate with a valid certificate that contains a SAN field then proceed with the vCenter Server 7.0 Upgrade/Migration.

Problems upgrading to vSphere 7.0 with pre-existing CIM providers

After upgrade, previously installed 32-bit CIM providers stop working because ESXi requires 64-bit CIM providers. Customers may lose management API functions related to CIMPDK, NDDK (native DDK), HEXDK, VAIODK (IO filters), and see errors related to **uwglibc** dependency.

The syslog reports module missing, "32 bit shared libraries not loaded."

Workaround: There is no workaround. The fix is to download new 64-bit CIM providers from your vendor.

Patching to vCenter Server 7.0 Update 1 from earlier versions of vCenter Server 7.x is blocked when vCenter Server High Availability is enabled

Patching to vCenter Server 7.0 Update 1 from earlier versions of vCenter Server 7.x is blocked when vCenter Server High Availability is active.

Workaround: To patch your system to vCenter Server 7.0 Update 1 from earlier versions of vCenter Server 7.x, you must remove vCenter Server High Availability and delete the passive and witness nodes. After the upgrade, you must re-create your vCenter Server High Availability clusters.

Migration of a 6.7.x vCenter Server system to vCenter Server 7.x fails with an UnicodeEncodeError

If you select the option to import all data for configuration, inventory, tasks, events, and performance metrics, the migration of a 6.7.x vCenter Server system to vCenter Server 7.x might fail for any vCenter Server system that uses a non-English locale. At step 1 of stage 2 of the migration, in the vSphere Client, you see an error such as:

```
Error while exporting events and tasks data: …ERROR UnicodeEncodeError: Traceback (most recent call last):
```

Workaround: You can complete the migration operation by doing either:

- Select the default option **Configuration and Inventory** at the end of stage 1 of the migration. This option does not include tasks and events data.
- Clean the data in the events tables and run the migration again.

If a Windows vCenter Server system has a database password containing non-ASCII characters, pre-checks of the VMware Migration Assistant fail

If you try to migrate a 6.x vCenter Server system to vCenter Server 7.x by using the VMware Migration Assistant, and your system has a Windows OS, and uses an external database with a password containing non-ASCII characters, the operation fails. For example, Admin!23迁移. In the Migration Assistant console, you see the following error:

```
Error:Component com.vmware.vcdb failed with internal errorResolution:File Bugzilla PR to VPX/VPX/vcdb-upgrade
```

Workaround: None

During an update from vCenter Server 7.x to vCenter Server 7.0 Update 1, you get prompts to provide the vCenter Single Sign-On password

During an update from vCenter Server 7.x to vCenter Server 7.0 Update 1, you get prompts to provide vCenter Single Sign-On administrator password.

Workaround: If you run the update by using the vCenter Server Management Interface, you must provide the vCenter Single Sign-On administrator password.

If you run the update by using software-packages or CLI in an interactive manner, you must interactively provide the vCenter Single Sign-On administrator password.

If you run the update by using software-packages or CLI in a non-interactive manner, you must provide the vCenter Single Sign-On administrator password by an answer file in the format

```
{ "vmdir.password": "SSO Password of Administrator@<SSO-DOMAIN> user" }
```

Smart Card and RSA SecurID authentication might stop working after upgrading to vCenter Server 7.0

If you have configured vCenter Server for either Smart Card or RSA SecurID authentication, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057 before starting the vSphere 7.0 upgrade process. If you do not perform the workaround as described in the KB, you might see the following error messages and Smart Card or RSA SecurID authentication does not work.

"Smart card authentication may stop working. Smart card settings may not be preserved, and smart card authentication may stop working."

or

"RSA SecurID authentication may stop working. RSA SecurID settings may not be preserved, and RSA SecurID authentication may stop working."

Workaround: Before upgrading to vSphere 7.0, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057.

You might not be able to apply or remove NSX while you add ESXi hosts by using a vSphere Lifecycle Manager image to a cluster with enabled VMware vSphere High Availability

If you start an operation to apply or remove NSX while adding multiple ESXi hosts by using a vSphere Lifecycle Manager image to a vSphere HA-enabled cluster, the NSX-related operations might fail with an error in the vSphere Client such as:

```
vSphere HA agent on some of the hosts on cluster <cluster_name> is neither vSphere HA master agent nor connected to vSphere HA master agent. Verify that the HA configuration is correct.
```

The issue occurs because vSphere Lifecycle Manager configures vSphere HA for the ESXi hosts being added to the cluster one at a time. If you run an operation to apply or remove NSX while vSphere HA configure operations are still in progress, NSX operations might queue up between the vSphere HA configure operations for two different ESXi hosts. In such a case, the NSX operation fails with a cluster health check error, because the state of the cluster at that point does not match the expected state that all ESXi hosts have vSphere HA configured and running. The more ESXi hosts you add to a cluster at the same time, the more likely the issue is to occur.

Workaround: Deactivate and enable Sphere HA on the cluster. Proceed with the operations to apply or remove NSX.

After an upgrade of a vCenter Server 7.0 system, you cannot see the IP addresses of pods in the vSphere Pod Summary tab of the vSphere Client

If you upgrade your vCenter Server 7.0 system to a later version, you can no longer see the IP addresses of pods in the **vSphere Pod Summary** tab of the vSphere Client.

Workaround: Use the Kubernetes CLI Tools for vSphere to review details of pods:

1. As a prerequisite, copy the pod and namespace names.
   - In the vSphere Client, navigate to **Workload Management** > **Clusters.**
   - Copy the IP displayed in the **Control Plane Node IP Address** tab.
   - You can navigate to `https://<control_plane_node_IP_address>` and download the Kubernetes CLI Tools, `kubectl` and `kubectl-vsphere`.
     Alternatively, follow the steps in Download and Install the Kubernetes CLI Tools for vSphere.
2. Use the CLI plug-in for vSphere to review the pod details.
   a. Log in to the Supervisor cluster by using the command
      `kubectl vsphere login --server=https://<server_adress> --vsphere-username <your user account name> --insecure-skip-tls-verify`
   b. By using the names copied in step 1, run the commands for retrieving the pod details:
      `kubectl config use-context <namespace_name>`
      and
      `kubectl describe pod <pod_name> -n <namespace_name>`

As a result, you can see the IP address in an output similar to:

```
$ kubectl describe pod helloworld -n my-podvm-ns ...

Status: Running

IP: 10.0.0.10

IPs:

IP: 10.0.0.10 ...
```

Upgrading a vCenter Server with an external Platform Services Controller from 6.7u3 to 7.0 fails with VMAFD error

When you upgrade a vCenter Server deployment using an external Platform Services Controller, you converge the Platform Services Controller into a vCenter Server appliance. If the upgrade fails with the error `install.vmafd.vmdir_vdcpromo_error_21`, the VMAFD firstboot process has failed. The VMAFD firstboot process copies the VMware Directory Service Database (data.mdb) from the source Platform Services Controller and replication partner vCenter Server appliance.

Workaround: Deactivate TCP Segmentation Offload (TSO) and Generic Segmentation Offload (GSO) on the Ethernet adapter of the source Platform Services Controller or replication partner vCenter Server appliance before upgrading a vCenter Server with an external Platform Services Controller. See Knowledge Base article: https://kb.vmware.com/s/article/74678

vCenter Server system upgrades fail in the pre-check stage

Upgrades of your vCenter Server system might fail in the pre-check stage due to a limit in the authorization (Authz) connections. In the `/var/log/vmware/vpxd-svcs/vpxd-svcs*.log` file you see entries such as:

`Session count for user [after add]: <DOMAIN-NAME>\machine-xxxx is 200Session limit reached for user: <DOMAIN-NAME>\machine-xxxx with 200 sessions.`

You might also see delayed response from the vSphere Client to load the inventory.

Workaround: Restart vmware-vpxd-svcs in your vCenter Server system by using the command `service-control --restart vmware-vpxd-svcs` . Use the command only when no other activity runs in the vCenter Server system to avoid any interruptions to the workflow. For more information, see VMware knowledge base article 81953.

Upgrading vCenter Server using the CLI incorrectly preserves the Transport Security Layer (TLS) configuration for the vSphere Authentication Proxy service

If the vSphere Authentication Proxy service (`vmcam`) is configured to use a particular TLS protocol other than the default TLS 1.2 protocol, this configuration is preserved during the CLI upgrade process. By default, vSphere supports the TLS 1.2 encryption protocol. If you must use the TLS 1.0 and TLS 1.1 protocols to support products or services that do not support TLS 1.2, use the TLS Configurator Utility to enable or deactivate different TLS protocol versions.

Workaround: Use the TLS Configurator Utility to configure the `vmcam` port. To learn how to manage TLS protocol configuration and use the TLS Configurator Utility, see the *VMware Security* documentation.

You do not see a precheck error when patching to vCenter Server 7.0 Update 3c by using CLI

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3c adds an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. In some cases, if such hosts exist in your system, patching from an vCenter Server version earlier than 7.0 Update 3 to a version later than 7.0 Update 3 by using CLI might fail with the error `Installation failed. Retry to resume from the current state. Or please collect the VC support bundle..`

However, instead of this error, you must see the precheck error message.

Workaround: If you do not see the precheck error and patching your system to vCenter Server 7.0 Update 3c fails, make sure all ESXi hosts are upgraded to ESXi 7.0 Update 3c or higher, by using either a baseline created from an ISO or a single image, before upgrading vCenter Server. Do not use patch baselines based on the rollup bulletin. You can find additional debug log information at `/var/log/vmware/applmgmt` . For more details, see VMware knowledge base articles 87319 and 86447.

Smart card and RSA SecurID settings may not be preserved during vCenter Server upgrade

Authentication using RSA SecurID will not work after upgrading to vCenter Server 7.0. An error message will alert you to this issue when attempting to login using your RSA SecurID login.

Workaround: Reconfigure the smart card or RSA SecureID.

Upgrade to vSphere 7.0 Update 3c might require additional steps to force a full host-sync

The supported upgrade sequence for vSphere systems is first to upgrade vCenter Server and then ESXi. However, in certain environments with ESXi hosts of version 7.0 Update 2c and later, you need to update ESXi first to 7.0 Update 3c and then vCenter Server. Such an upgrade sequence requires additional steps to force a full host-sync.

Workaround: Log in to the appliance shell as a user with super administrative privileges (for example, `root`) and follow these steps:

1. Stop the vpxd service.

2. Run the command `/opt/vmware/vpostgres/current/bin/psql -U postgres -d VCDB -c "update VPX_HOST_SYNC_GEN set master_gen=0 where host_id in (select id from VPX_HOST where product_version like '7.0.3%')"`.
3. Start the vpxd service.

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with network error message

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with the error message `IP already exists in the network`. This prevents the migration process from configuring the network parameters on the new vCenter Server appliance. For more information, examine the log file: `/var/log/vmware/upgrade/UpgradeRunner.log`

Workaround:

1. Verify that all Windows Updates have been completed on the source vCenter Server for Windows instance, or deactivate automatic Windows Updates until after the migration finishes.
2. Retry the migration of vCenter Server for Windows to vCenter Server appliance 7.0.

Hot-patched ESXi hosts with both i40en and i40enu Intel network drivers installed might fail to configure vSphere High Availability after upgrade to vCenter Server 7.0 Update 3c

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3c adds an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. However, if you apply an ESXi hot patch that is released after vCenter Server 7.0 Update 3c and then upgrade your system to vCenter Server 7.0 Update 3c, the hot patch might not be listed in the precheck. As a result, you might not follow the proper steps to the upgrade and vSphere HA might fail to configure on such hosts.

Workaround: Upgrade the hot-patched ESXi hosts to version 7.0 Update 3c.

When you configure the number of virtual functions for an SR-IOV device by using the max_vfs module parameter, the changes might not take effect

In vSphere 7.0, you can configure the number of virtual functions for an SR-IOV device by using the Virtual Infrastructure Management (VIM) API, for example, through the vSphere Client. The task does not require reboot of the ESXi host. After you use the VIM API configuration, if you try to configure the number of SR-IOV virtual functions by using the `max_vfs` module parameter, the changes might not take effect because they are overridden by the VIM API configuration.

Workaround: None. To configure the number of virtual functions for an SR-IOV device, use the same method every time. Use the VIM API or use the `max_vfs` module parameter and reboot the ESXi host.

Upgraded vCenter Server appliance instance does not retain all the secondary networks (NICs) from the source instance

During a major upgrade, if the source instance of the vCenter Server appliance is configured with multiple secondary networks other than the VCHA NIC, the target vCenter Server instance will not retain secondary networks other than the VCHA NIC. If the source instance is configured with multiple NICs that are part of VDS port groups, the NIC configuration will not be preserved during the upgrade. Configurations for vCenter Server appliance instances that are part of the standard port group will be preserved.

Workaround: None. Manually configure the secondary network in the target vCenter Server appliance instance.

After upgrading or migrating a vCenter Server with an external Platform Services Controller, users authenticating using Active Directory lose access to the newly upgraded vCenter Server instance

After upgrading or migrating a vCenter Server with an external Platform Services Controller, if the newly upgraded vCenter Server is not joined to an Active Directory domain, users authenticating using Active Directory will lose access to the vCenter Server instance.

Workaround: Verify that the new vCenter Server instance has been joined to an Active Directory domain. See Knowledge Base article: https://kb.vmware.com/s/article/2118543

Migrating a vCenter Server for Windows with an external Platform Services Controller using an Oracle database fails

If there are non-ASCII strings in the Oracle events and tasks table the migration can fail when exporting events and tasks data. The following error message is provided: UnicodeDecodeError

Workaround: None.

After an ESXi host upgrade, a Host Profile compliance check shows non-compliant status while host remediation tasks fail

The non-compliant status indicates an inconsistency between the profile and the host.

This inconsistency might occur because ESXi 7.0 does not allow duplicate claim rules, but the profile you use contains duplicate rules. For example, if you attempt to use the Host Profile that you extracted from the host before upgrading ESXi 6.5 or ESXi 6.7 to version 7.0 and the Host Profile contains any duplicate claim rules of system default rules, you might experience the problems.

Workaround:

1. Remove any duplicate claim rules of the system default rules from the Host Profile document.
2. Check the compliance status.
3. Remediate the host.
4. If the previous steps do not help, reboot the host.

Error message displays in the vCenter Server Management Interface

After installing or upgrading to vCenter Server 7.0, when you navigate to the Update panel within the vCenter Server Management Interface, the error message "Check the URL and try again" displays. The error message does not prevent you from using the functions within the Update panel, and you can view, stage, and install any available updates.

Workaround: None.

Patching witness or passive nodes of environments with VMware vCenter Server High Availability enabled might fail

In environments with vCenter Server High Availability enabled, patching a witness or passive node might fail with a message similar to:

```
RuntimeError: unidentifiable C++ exception.
```

Workaround: Deactivate vCenter Server High Availability. Apply patches to your vCenter Server system. Re-enable vCenter Server High Availability.

After patching your vCenter Server system to vCenter Server 7.0.0a, the TLS version of the VC Storage Clients might revert to the default

If you have a TLS configuration for the VC Storage Clients service different from the default TLS 1.2 only, the TLS version might revert to the default after patching your vCenter Server system to vCenter Server 7.0.0a.

Workaround: Use the TLS Configuration utility to enable or deactivate TLS versions on your vCenter Server system after the update.

After updating your system to vCenter Server 7.0.0b, you see systemd core dump in the /var/core folder

After updating your system to vCenter Server 7.0.0b from either vCenter Server 7.0.0a or vCenter Server 7.0, in the `/var/core` folder you see systemd core dump, such as `core.systemd-journal.393` and `core.systemd-udevd.405` . The core dump is harmless and can be removed.

Workaround: None

After updating your vCenter Server system to 7.0.0b, the vCenter Server version is not updated in the Direct Console User Interface (DCUI)

After updating your system to vCenter Server 7.0.0b from vCenter Server 7.0.0a or vCenter Server 7.0, you still see the previous vCenter Server version in the DCUI.

Workaround: After you complete the update, to refresh the vCenter Server version, in the appliance shell, run the command `/usr/lib/applmgmt/dcui/notify` .

Update Planner fails with error Configured repository is not accessible due to network connectivity or incorrect URL

If you use Update Planner, which is part of vSphere Lifecycle Manager used to facilitate vCenter Server updates, you might see the following error in the vSphere Client:

`Configured repository is not accessible due to network connectivity or incorrect URL. Verify the repository settings.`

The issue occurs when you use a custom local repository, such as `https:///uploads/dpe/` or a DBC path, to store the extracted . If the custom repository for URL-based patching has an authentication policy, Update Planner might not be able to fetch the list of available updates.

Workaround: Configure the custom repository such that authentication is not needed to access the custom repository URL.

After upgrading to vCenter Server 7.0.0b, you see vSphere HA errors on vSphere Lifecycle Manager Image based clusters

After upgrading to vCenter Server 7.0.0b, on vSphere Lifecycle Manager Image based clusters that are configured with vSphere HA, you might see error messages about the vSphere HA configuration after logging in for the first time to the environment. In the vSphere Client, you see messages such as:

`Cannot complete the configuration of the vSphere HA agent on the host.` or

`Applying HA VIBs on the cluster encountered a failure.`

The issue occurs because exports of the image depot might take long and cause a timeout of the task. In the`/storage/log/vmware/vmware-updatemgr/vum-server/vmware-vum-server.log` you see this message: `Export taking too long (Failure case)`

Workaround: This is a transient issue that resolves in 10 minutes after the vCenter Server is up and running. The issue does not affect any functionality. vSphere HA on the affected clusters operates as expected. All operations related to virtual machines, such as power on and migration, work across the vSphere HA-enabled clusters while this error recovery is still in progress.

You do not see a precheck error when patching to vCenter Server 7.0 Update 3d by using CLI

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3d and later add an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. In some cases, if such hosts exist in your system, patching from a vCenter Server version earlier than 7.0 Update 3 to a version later than 7.0 Update 3 by using CLI might fail with the error `Installation failed. Retry to resume from the current state. Or please collect the VC support bundle.` . However, instead of this error, you must see the precheck error message.

Workaround: If you do not see the precheck error and patching your system to vCenter Server 7.0 Update 3d fails, make sure all ESXi hosts are upgraded to ESXi 7.0 Update 3d, by using either a baseline created from an ISO or a single image, before upgrading vCenter Server. Do not use patch baselines based on the rollup bulletin. You can find additional debug log information at `/var/log/vmware/applmgmt` . For more details, see VMware knowledge base articles 87319 and 86447.

Security Features Issues

Encrypted virtual machine fails to power on when HA-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled HA on the Trusted Cluster and one or more hosts in the cluster fails attestation, an encrypted virtual machine cannot power on.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Encrypted virtual machine fails to power on when DRS-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled DRS on the Trusted Cluster and one or more hosts in the cluster fails attestation, DRS might try to power on an encrypted virtual machine on an unattested host in the cluster. This operation puts the virtual machine in a locked state.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Migrating or cloning encrypted virtual machines across vCenter Server instances fails when attempting to do so using the vSphere Client

If you try to migrate or clone an encrypted virtual machine across vCenter Server instances using the vSphere Client, the operation fails with the following error message: "The operation is not allowed in the current state."

Workaround: You must use the vSphere APIs to migrate or clone encrypted virtual machines across vCenter Server instances.

Networking Issues

PR3304411: After batch cloning and customizing Windows virtual machines, the VMs network might not be configured

When cloning Windows VMs in bulk, a MAC address conflict might occur, causing vCenter to reassign new MAC addresses to the VMs. As a result, the guest customization process fails to configure properly the VMs network because it cannot match the original MAC address to the corresponding network card.

This issue is resolved in this release.

When you use the VMware Remote Console, the envoy service might intermittently fail

An issue with the envoy service specific to the VMware Remote Console might lead to intermittent failures of the service. As a result, the vCenter Server Management Interface or vCenter Server APIs might also become unavailable.

Workaround: Use the vSphere Client as an alternative to the VMware Remote Console.

Reduced throughput in networking performance on Intel 82599/X540/X550 NICs

The new queue-pair feature added to ixgben driver to improve networking performance on Intel 82599EB/X540/X550 series NICs might reduce throughput under some workloads in vSphere 7.0 as compared to vSphere 6.7.

Workaround: To achieve the same networking performance as vSphere 6.7, you can deactivate the queue-pair with a module parameter. To deactivate the queue-pair, run the command:

```
# esxcli system module parameters set -p "QPair=0,0,0,0..." -m ixgben
```

After running the command, reboot.

If you try to deactivate vSphere with Tanzu on a vSphere cluster, the operation stops with an error

If some virtual machines outside of a Supervisor Cluster reside on any of the NSX segment port groups on the cluster, the cleanup script cannot delete such ports and deactivate vSphere with Tanzu on the cluster. In the vSphere Client, you see the error `Cleanup requests to NSX Manager failed` and the operation stops at `Removing` status. In the `/var/log/vmware/wcp/wcpsvc.log` file, you see an error message such as

```
Segment path=[...] has x VMs or VIFs attached. Disconnect all VMs and VIFs before deleting a segment.
```

Workaround: Delete the virtual machines indicated in the `/var/log/vmware/wcp/wcpsvc.log` file from the segment. Wait for the operation to restore.

After upgrading to NSX 6.4.7, when a static IPv6 address is assigned to workload VMs on an IPv6 network, the VMs are unable to ping the IPv6 gateway interface of the edge

This issue occurs after upgrading the vSphere Distributed Switches from 6.x to 7.0.

Workaround 1:

Select the VDS where all the hosts are connected, go to the **Edit** setting, and under **Multicast** option switch to basic.

Workaround 2:

Add the following rules on the edge firewall:

Ping allow rule.

Multicast Listener Discover (MLD) allow rule, which are icmp6, type 130 (v1) and type 143 (v2).

High throughput virtual machines may experience degradation in network performance when Network I/O Control (NetIOC) is enabled

Virtual machines requiring high network throughput can experience throughput degradation when upgrading from vSphere 6.7 to vSphere 7.0 with NetIOC enabled.

Workaround: Adjust the `ethernetx.ctxPerDev` setting to enable multiple worlds.

IPv6 traffic fails to pass through VMkernel ports using IPsec

When you migrate VMkernel ports from one port group to another, IPv6 traffic does not pass through VMkernel ports using IPsec.

Workaround: Remove the IPsec security association (SA) from the affected server, and then reapply the SA. To learn how to set and remove an IPsec SA, see the *vSphere Security* documentation.

Higher ESX network performance with a portion of CPU usage increase

ESX network performance may increase with a portion of CPU usage.

Workaround: Remove and add the network interface with only 1 rx dispatch queue. For example:

```
esxcli network ip interface remove --interface-name=vmk1
```

```
esxcli network ip interface add --interface-name=vmk1 --num-rxqueue=1
```

VM might lose Ethernet traffic after hot-add, hot-remove or storage vMotion

A VM might stop receiving Ethernet traffic after a hot-add, hot-remove or storage vMotion. This issue affects VMs where the uplink of the VNIC has SR-IOV enabled. PVRDMA virtual NIC exhibits this issue when the uplink of the virtual network is a Mellanox RDMA capable NIC and RDMA namespaces are configured.

Workaround: You can hot-remove and hot-add the affected Ethernet NICs of the VM to restore traffic. On Linux guest operating systems, restarting the network might also resolve the issue. If these workarounds have no effect, you can reboot the VM to restore network connectivity.

Change of IP address for a VCSA deployed with static IP address requires that you create the DNS records in advance

With the introduction of the DDNS, the DNS record update only works for VCSA deployed with DHCP configured networking. While changing the IP address of the vCenter server via VAMI, the following error is displayed:

The specified IP address does not resolve to the specified hostname.

Workaround: There are two possible workarounds.

1. Create an additional DNS entry with the same FQDN and desired IP address. Log in to the VAMI and follow the steps to change the IP address.
2. Log in to the VCSA using ssh. Execute the following script:
   `./opt/vmware/share/vami/vami_config_net`
   Use option 6 to change the IP adddress of eth0. Once changed, execute the following script:
   `./opt/likewise/bin/lw-update-dns`
   Restart all the services on the VCSA to update the IP information on the DNS server.

It may take several seconds for the NSX Distributed Virtual Port Group (NSX DVPG) to be removed after deleting the corresponding logical switch in NSX Manager.

As the number of logical switches increases, it may take more time for the NSX DVPG in vCenter Server to be removed after deleting the corresponding logical switch in NSX Manager. In an environment with 12000 logical switches, it takes approximately 10 seconds for an NSX DVPG to be deleted from vCenter Server.

Workaround: None.

Hostd runs out of memory and fails if a large number of NSX Distributed Virtual port groups are created.

In vSphere 7.0, NSX Distributed Virtual port groups consume significantly larger amounts of memory than opaque networks. For this reason, NSX Distributed Virtual port groups can not support the same scale as an opaque network given the same amount of memory.

Workaround:To support the use of NSX Distributed Virtual port groups, increase the amount of memory in your ESXi hosts. If you verify that your system has adequate memory to support your VMs, you can directly increase the memory of `hostd` using the following command.

```
localcli --plugin-dir /usr/lib/vmware/esxcli/int/ sched group setmemconfig --group-path
host/vim/vmvisor/hostd --units mb --min 2048 --max 2048
```

Note that this will cause `hostd` to use memory normally reserved for your environment's VMs. This may have the affect of reducing the number of VMs your ESXi host can support.

DRS may incorrectly launch vMotion if the network reservation is configured on a VM

If the network reservation is configured on a VM, it is expected that DRS only migrates the VM to a host that meets the specified requirements. In a cluster with NSX transport nodes, if some of the transport nodes join the transport zone by NSX-T Virtual Distributed Switch (N-VDS), and others by vSphere Distributed Switch (VDS) 7.0, DRS may incorrectly launch vMotion. You might encounter this issue when:

- The VM connects to an NSX logical switch configured with a network reservation.
- Some transport nodes join transport zone using N-VDS, and others by VDS 7.0, or, transport nodes join the transport zone through different VDS 7.0 instances.

Workaround: Make all transport nodes join the transport zone by N-VDS or the same VDS 7.0 instance.

When adding a VMkernel NIC (vmknic) to an NSX portgroup, vCenter Server reports the error "Connecting VMKernel adapter to a NSX Portgroup on a Stateless host is not a supported operation. Please use Distributed Port Group instead."

- For stateless ESXi on Distributed Virtual Switch (VDS), the vmknic on a NSX port group is blocked. You must instead use a Distributed Port Group.
- For stateful ESXi on VDS, vmknic on NSX port group is supported, but vSAN may have an issue if it is using vmknic on a NSX port group.

Workaround: Use a Distributed Port Group on the same VDS.

Enabling SRIOV from vCenter for QLogic 4x10GE QL41164HFCU CNA might fail

If you navigate to the **Edit Settings** dialog for physical network adapters and attempt to enable SR-IOV, the operation might fail when using QLogic 4x10GE QL41164HFCU CNA. Attempting to enable SR-IOV might lead to a network outage of the ESXi host.

Workaround: Use the following command on the ESXi host to enable SRIOV:

```
esxcfg-module
```

Storage Issues

VMFS datastores are not mounted automatically after disk hot remove and hot insert on HPE Gen10 servers with SmartPQI controllers

When SATA disks on HPE Gen10 servers with SmartPQI controllers without expanders are hot removed and hot inserted back to a different disk bay of the same machine, or when multiple disks are hot removed and hot inserted back in a different order, sometimes a new local name is assigned to the disk. The VMFS datastore on that disk appears as a snapshot and will not be mounted back automatically because the device name has changed.

Workaround: None. SmartPQI controller does not support unordered hot remove and hot insert operations.

ESXi might terminate I/O to NVMeOF devices due to errors on all active paths

Occasionally, all active paths to NVMeOF device register I/O errors due to link issues or controller state. If the status of one of the paths changes to Dead, the High Performance Plug-in (HPP) might not select another path if it shows high volume of errors. As a result, the I/O fails.

Workaround: Deactivate the configuration option **/Misc/HppManageDegradedPaths** to unblock the I/O.

VOMA check on NVMe based VMFS datastores fails with error

VOMA check is not supported for NVMe based VMFS datastores and will fail with the error:

```
ERROR: Failed to reserve device. Function not implemented
```

Example:

```
# voma -m vmfs -f check -d /vmfs/devices/disks/: <partition#>
Running VMFS Checker version 2.1 in check mode
Initializing LVM metadata, Basic Checks will be done

Checking for filesystem activity
Performing filesystem liveness check..|Scanning for VMFS-6 host activity (4096 bytes/HB, 1024 HBs).
ERROR: Failed to reserve device. Function not implemented
Aborting VMFS volume check
VOMA failed to check device : General Error
```

Workaround: None. If you need to analyse VMFS metadata, collect it using the `-l` option, and pass to VMware customer support. The command for collecting the dump is:

```
voma -l -f dump -d /vmfs/devices/disks/:<partition#>
```

Using the VM reconfigure API to attach an encrypted First Class Disk to an encrypted virtual machine might fail with error

If an FCD and a VM are encrypted with different crypto keys, your attempts to attach the encrypted FCD to the encrypted VM using the `VM reconfigure API` might fail with the error message:

```
Cannot decrypt disk because key or password is incorrect.
```

Workaround: Use the `attachDisk API` rather than the `VM reconfigure API` to attach an encrypted FCD to an encrypted VM.

ESXi host might get in non responding state if a non-head extent of its spanned VMFS datastore enters the Permanent Device Loss (PDL) state

This problem does not occur when a non-head extent of the spanned VMFS datastore fails along with the head extent. In this case, the entire datastore becomes inaccessible and no longer allows I/Os.

In contrast, when only a non-head extent fails, but the head extent remains accessible, the datastore heartbeat appears to be normal. And the I/Os between the host and the datastore continue. However, any I/Os that depend on the failed non-head extent start failing as well. Other I/O transactions might accumulate while waiting for the failing I/Os to resolve, and cause the host to enter the non responding state.

Workaround: Fix the PDL condition of the non-head extent to resolve this issue.

After recovering from APD or PDL conditions, VMFS datastore with enabled support for clustered virtual disks might remain inaccessible

You can encounter this problem only on datastores where the clustered virtual disk support is enabled. When the datastore recovers from an All Paths Down (APD) or Permanent Device Loss (PDL) condition, it remains inaccessible. The VMkernel log might show multiple `SCSI3 reservation conflict` messages similar to the following:

```
2020-02-18T07:41:10.273Z cpu22:1001391219)ScsiDeviceIO: vm 1001391219:
SCSIDeviceCmdCompleteCB:2972: Reservation conflict retries 544 for command 0x45ba814b8340
(op: 0x89) to device "naa.624a9370b97601e346f64ba900024d53"
```

The problem can occur because the ESXi host participating in the cluster loses SCSI reservations for the datastore and cannot always reacquire them automatically after the datastore recovers.

Workaround: Manually register the reservation using the following command:

```
vmkfstools -L registerkey /vmfs/devices/disks/<device name>
```

where the `<device name>` is the name of the device on which the datastore is created.

Virtual NVMe Controller is the default disk controller for Windows 10 guest operating systems

The Virtual NVMe Controller is the default disk controller for the following guest operating systems when using Hardware Version 15 or later:

Windows 10

Windows Server 2016

Windows Server 2019

Some features might not be available when using a Virtual NVMe Controller. For more information, see https://kb.vmware.com/s/article/2147714

Note: Some clients use the previous default of LSI Logic SAS. This includes ESXi host client and PowerCLI.

Workaround: If you need features not available on Virtual NVMe, switch to VMware Paravirtual SCSI (PVSCSI) or LSI Logic SAS. For information on using VMware Paravirtual SCSI (PVSCSI), see https://kb.vmware.com/s/article/1010398

After an ESXi host upgrade to vSphere 7.0, presence of duplicate core claim rules might cause unexpected behavior

Claim rules determine which multipathing plugin, such as NMP, HPP, and so on, owns paths to a particular storage device. ESXi 7.0 does not support duplicate claim rules. However, the ESXi 7.0 host does not alert you if you add duplicate rules to the existing claim rules inherited through an upgrade from a legacy release. As a result of using duplicate rules, storage devices might be claimed by unintended plugins, which can cause unexpected outcome.

Workaround: Do not use duplicate core claim rules. Before adding a new claim rule, delete any existing matching claim rule.

A CNS query with the compliance status filter set might take unusually long time to complete

The CNS QueryVolume API enables you to obtain information about the CNS volumes, such as volume health and compliance status. When you check the compliance status of individual volumes, the results are obtained quickly. However, when you invoke the CNS QueryVolume API to check the compliance status of multiple volumes, several tens or hundreds, the query might perform slowly.

Workaround: Avoid using bulk queries. When you need to get compliance status, query one volume at a time or limit the number of volumes in the query API to 20 or fewer. While using the query, avoid running other CNS operations to get the best performance.

New Deleted CNS volumes might temporarily appear as existing in the CNS UI

After you delete an FCD disk that backs a CNS volume, the volume might still show up as existing in the CNS UI. However, your attempts to delete the volume fail. You might see an error message similar to the following:

```
The object or item referred to could not be found.
```

Workaround: The next full synchronization will resolve the inconsistency and correctly update the CNS UI.

New Under certain circumstances, while a CNS operation fails, the task status appears as successful in the vSphere Client

This might occur when, for example, you use an incompliant storage policy to create a CNS volume. The operation fails, while the vSphere Client shows the task status as successful.

Workaround: The successful task status in the vSphere Client does not guarantee that the CNS operation succeeded. To make sure the operation succeeded, verify its results.

New Unsuccessful delete operation for a CNS persistent volume might leave the volume undeleted on the vSphere datastore

This issue might occur when the CNS Delete API attempts to delete a persistent volume that is still attached to a pod. For example, when you delete the Kubernetes namespace where the pod runs. As a result, the volume gets cleared from CNS and the CNS query operation does not return the volume. However, the volume continues to reside on the datastore and cannot be deleted through the repeated CNS Delete API operations.

Workaround: None.

vCenter Server and vSphere Client Issues

PR 3262556: vCenter upgrade fails with "VP last sync time not updated after waiting for 5 minutes after vCenter update"

In rare cases, during a vCenter upgrade, a race condition between vSphere API for Storage Awareness (VASA) providers might cause the upgrade to fail. In the `pod-service.log` file, you see an error such as `vSAN VP last sync time not updated after waiting for 5 minutes after vCenter update.`

This issue is resolved in this release. The fix prevents the race condition.

You do not see the VLAN ID in the port properties page of a VMkernel network adapter in the vSphere Client

In the vSphere Client, when you follow the path **Host > Add Networking**, after you select a VMkernel network adapter and an existing standard switch, in the **Port properties** page you might not see the VLAD ID. The issue occurs because the VLAN ID component is part of the `network-ui` module, which is lazy loaded and needs a trigger to refresh.

Workaround: Go to **Host > Configure > Networking > Virtual Switches** to trigger the loading of the `network ui` module and the VLAD ID appears.

Vendor providers go offline after a PNID change

When you change the vCenter IP address (PNID change), the registered vendor providers go offline.

Workaround: Re-register the vendor providers.

Cross vCenter migration of a virtual machine fails with an error

When you use cross vCenter vMotion to move a VM's storage and host to a different vCenter server instance, you might receive the error `The operation is not allowed in the current state.`

This error appears in the UI wizard after the Host Selection step and before the Datastore Selection step, in cases where the VM has an assigned storage policy containing host-based rules such as encryption or any other IO filter rule.

Workaround: Assign the VM and its disks to a storage policy without host-based rules. You might need to decrypt the VM if the source VM is encrypted. Then retry the cross vCenter vMotion action.

Storage Sensors information in Hardware Health tab shows incorrect values on vCenter UI, host UI, and MOB

When you navigate to **Host > Monitor > Hardware Health > Storage Sensors** on vCenter UI, the storage information displays either incorrect or unknown values. The same issue is observed on the host UI and the MOB path `"runtime.hardwareStatusInfo.storageStatusInfo"` as well.

Workaround: None.

vSphere UI host advanced settings shows the current product locker location as empty with an empty default

vSphere UI host advanced settings shows the current product locker location as empty with an empty default. This is inconsistent as the actual product location `symlink` is created and valid. This causes confusion to the user. The default cannot be corrected from UI.

Workaround: User can use the esxcli command on the host to correct the current product locker location default as below.

1. Remove the existing Product Locker Location setting with: `"esxcli system settings advanced remove -o ProductLockerLocation"`

2. Re-add the Product Locker Location setting with the appropriate default:

2.a. If the ESXi is a full installation, the default value is `"/locker/packages/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/locker/packages/vmtoolsRepo"`

2.b. If the ESXi is a PXEboot configuration such as autodeploy, the default value is: `"/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/vmtoolsRepo"`

Run the following command to automatically figure out the location: `export PRODUCT_LOCKER_DEFAULT=`readlink /productLocker``

Add the setting: `esxcli system settings advanced add -d "Path to VMware Tools repository" -o ProductLockerLocation -t string -s $PRODUCT_LOCKER_DEFAULT`

You can combine all the above steps in step 2 by issuing the single command:

```
esxcli system settings advanced add -d "Path to VMware Tools repository" -o
ProductLockerLocation -t string -s `readlink /productLocker`
```

Skyline Health page displays garbage characters

In the vSphere Client, when you navigate to vCenter Server or select an ESXi host in the vSphere Client navigator and click Monitor > Skyline Health, the page displays garbage characters in the following locales: Korean, Japanese, German and French.

Workaround: Switch to English locale.

Virtual Machine Management Issues

You cannot add or modify an existing network adapter on a virtual machine

If you try to add or modify an existing network adapter on a virtual machine, the Reconfigure Virtual Machine task might fail with an error such as `Cannot complete operation due to concurrent modification by another operation` in the vSphere Client. In the `/var/log/hostd.log` file of the ESXi host where the virtual machine runs, you see logs such as:

```
2020-07-28T07:47:31.621Z verbose hostd[2102259] [Originator@6876 sub=Vigor.Vmsvc.vm:/
vmfs/volumes/vsan:526bc94351cf8f42-41153841cab2f9d9/bad71f5f-d85e-a276-4cf6-246e965d7154/
interop_l2vpn_vmotion_VM_1.vmx] NIC: connection control message: Failed to connect virtual
device 'ethernet0'.
```

In the `vpxa.log` file, you see entries similar to: `2020-07-28T07:47:31.941Z info vpxa[2101759] [Originator@6876 sub=Default opID=opId-59f15-19829-91-01-ed] [VpxLRO] -- ERROR task-138 -- vm-13 -- vim.VirtualMachine.reconfigure: vim.fault.GenericVmConfigFault:`

Workaround: For each ESXi host in your cluster do the following:

1. Connect to the ESXi host by using SSH and run the command
   `esxcli system module parameters set -a -p dvfiltersMaxFilters=8192 -m dvfilter`
2. Put the ESXi host in Maintenance Mode.
3. Reboot the ESXi host.

For more information, see VMware knowledge base article 80399.

ESXi 6.5 hosts with AMD Opteron Generation 3 (Greyhound) processors cannot join Enhanced vMotion Compatibility (EVC) AMD REV E or AMD REV F clusters on a vCenter Server 7.0 Update 1 system

In vCenter Server 7.0 Update 1, vSphere cluster services, such as vSphere DRS and vSphere HA, run on ESX agent virtual machines to make the services functionally independent of vCenter Server. However, the CPU baseline for AMD processors of the ESX agent virtual machines have POPCNT SSE4A instructions, which prevents ESXi 6.5 hosts with AMD Opteron Generation 3 (Greyhound) processors to enable EVC mode AMD REV E and AMD REV F on a vCenter Server 7.0 Update 1 system.

Workaround: None

The postcustomization section of the customization script runs before the guest customization

When you run the guest customization script for a Linux guest operating system, the `precustomization` section of the customization script that is defined in the customization specification runs before the guest customization and the `postcustomization` section runs after that. If you enable Cloud-Init in the guest operating system of a virtual machine, the `postcustomization` section runs before the customization due to a known issue in Cloud-Init.

Workaround: Deactivate Cloud-Init and use the standard guest customization.

Group migration operations in vSphere vMotion, Storage vMotion, and vMotion without shared storage fail with error

When you perform group migration operations on VMs with multiple disks and multi-level snapshots, the operations might fail with the error `com.vmware.vc.GenericVmConfigFault Failed waiting for data. Error 195887167. Connection closed by remote host, possibly due to timeout.`

Workaround: Retry the migration operation on the failed VMs one at a time.

Deploying an OVF or OVA template from a URL fails with a 403 Forbidden error

The URLs that contain an HTTP query parameter are not supported. For example, `http://webaddress.com?file=abc.ovf` or the Amazon pre-signed S3 URLs.

Workaround: Download the files and deploy them from your local file system.

Importing or deploying local OVF files containing non-ASCII characters in their name might fail with an error

When you import local `.ovf` files containing non-ASCII characters in their name, you might receive `400 Bad Request Error` . When you use such `.ovf` files to deploy a virtual machine in the vSphere Client, the deployment process stops at 0%. As a result, you might receive `400 Bad Request Error` or `500 Internal Server Error` .

Workaround:

1. Remove the non-ASCII characters from the `.ovf` and `.vmdk` file names.
   - To edit the `.ovf` file, open it with a text editor.
   - Search the non-ASCII `.vmdk` file name and change it to ASCII.
2. Import or deploy the saved files again.

New The third level of nested objects in a virtual machine folder is not visible

Perform the following steps:

1. Navigate to a data center and create a virtual machine folder.
2. In the virtual machine folder, create a nested virtual machine folder.
3. In the second folder, create another nested virtual machine, virtual machine folder, vApp, or VM Template.

As a result, from the VMs and Templates inventory tree you cannot see the objects in the third nested folder.

Workaround: To see the objects in the third nested folder, navigate to the second nested folder and select the VMs tab.

vSAN file services operations fail on vSphere Lifecycle Manager-enabled clusters

During a change in the state of an ESXi host, vSAN file services operations might fail on vSphere Lifecycle Manager-enabled clusters due to a race condition with the vSphere ESX Agent Manager (EAM). The problem happens during upgrades and operations, such as power on or power off, booting, or when the host exits maintenance or standby mode. The race condition occurs when an endpoint has been unavailable before the change of state of the ESXi host. In such cases, the EAM starts a remediation process that cannot be resolved and fails operations from other services, such as the vSAN file services.

Workaround: Restart the vSphere ESX Agent Manager.

vSphere HA and Fault Tolerance Issues

VMs in a cluster might be orphaned after recovering from storage inaccessibility such as a cluster wide APD

Some VMs might be in orphaned state after cluster wide APD recovers, even if HA and VMCP are enabled on the cluster.

This issue might be encountered when the following conditions occur simultaneously:

- All hosts in the cluster experience APD and do not recover until VMCP timeout is reached.
- HA primary initiates failover due to APD on a host.
- Power on API during HA failover fails due to one of the following:
  - APD across the same host
  - Cascading APD across the entire cluster
  - Storage issues
  - Resource unavailability
- FDM unregistration and VCs steal VM logic might initiate during a window where FDM has not unregistered the failed VM and VC's host synchronization responds that multiple hosts are reporting the same VM. Both FDM and VC unregister the different registered copies of the same VM from different hosts, causing the VM to be orphaned.

Workaround: You must unregister and reregister the orphaned VMs manually within the cluster after the APD recovers.

If you do not manually reregister the orphaned VMs, HA attempts failover of the orphaned VMs, but it might take between 5 to 10 hours depending on when APD recovers.

The overall functionality of the cluster is not affected in these cases and HA will continue to protect the VMs. This is an anomaly in what gets displayed on VC for the duration of the problem.

vSphere Lifecycle Manager Issues

vSphere Lifecycle Manager and vSAN File Services cannot be simultaneously enabled on a vSAN cluster in vSphere 7.0 release

If vSphere Lifecycle Manager is enabled on a cluster, vSAN File Services cannot be enabled on the same cluster and vice versa. In order to enable vSphere Lifecycle Manager on a cluster, which has VSAN File Services enabled already, first deactivate vSAN File Services and retry the operation. Please note that if you transition to a cluster that is managed by a single image, vSphere Lifecycle Manager cannot be deactivated on that cluster.

Workaround: None.

You cannot edit the VMware vSphere Lifecycle Manager Update Download scheduled task

In the vSphere Client, when you navigate to a vCenter Server instance and select **Scheduled Tasks** under the **Configure** tab, if you select the **VMware vSphere Lifecycle Manager Update Download** task and click **Edit**, you cannot modify the existing settings.

Workaround: You can edit the **VMware vSphere Lifecycle Manager Update Download** task by following the steps in the topic Configure the vSphere Lifecycle Manager Automatic Download Task.

When a hardware support manager is unavailable, vSphere High Availability (HA) functionality is impacted

If hardware support manager is unavailable for a cluster that you manage with a single image, where a firmware and drivers addon is selected and vSphere HA is enabled, the vSphere HA functionality is impacted. You may experience the following errors.

- Configuring vSphere HA on a cluster fails.
- Cannot complete the configuration of the vSphere HA agent on a host: `Applying HA VIBs on the cluster encountered a failure.`
- Remediating vSphere HA fails: `A general system error occurred: Failed to get Effective Component map.`

- Disabling vSphere HA fails: Delete Solution task failed. `A general system error occurred: Cannot find hardware support package from depot or hardware support manager.`

Workaround:

- If the hardware support manager is temporarily unavailable, perform the following steps.

1. Reconnect the hardware support manager to vCenter Server.
2. Select a cluster from the Hosts and Cluster menu.
3. Select the Configure tab.
4. Under Services, click vSphere Availability.
5. Re-enable vSphere HA.

- If the hardware support manager is permanently unavailable, perform the following steps.

1. Remove the hardware support manager and the hardware support package from the image specification
2. Re-enable vSphere HA.
3. Select a cluster from the Hosts and Cluster menu.
4. Select the Updates tab.
5. Click Edit .
6. Remove the firmware and drivers addon and click Save.
7. Select the Configure tab.
8. Under Services, click vSphere Availability.
9. Re-enable vSphere HA.

I/OFilter is not removed from a cluster after a remediation process in vSphere Lifecycle Manager

Removing I/OFilter from a cluster by remediating the cluster in vSphere Lifecycle Manager, fails with the following error message: `iofilter XXX already exists` . The iofilter remains listed as installed.

Workaround:

1. Call IOFilter API `UninstallIoFilter_Task` from the vCenter Server managed object (IoFilterManager).
2. Remediate the cluster in vSphere Lifecycle Manager.
3. Call IOFilter API `ResolveInstallationErrorsOnCluster_Task` from the vCenter Server managed object (IoFilterManager) to update the database.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, disabling and re-enabling vSphere HA causes a vSphere HA error state

Disabling and re-enabling vSphere HA during remediation process of a cluster, may fail the remediation process due to vSphere HA health checks reporting that hosts don't have vSphere HA VIBs installed. You may see the following error message: `Setting desired image spec for cluster failed.`

Workaround: After the cluster remediation operation has finished, deactivate and re-enable vSphere HA for the cluster.

Checking for recommended images in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the recommendation generation task could take more than an hour to finish or may appear to hang. The completion time for the recommendation task depends on the number of devices configured on each host and the number of image candidates from the depot that vSphere Lifecycle Manager needs to process before obtaining a valid image to recommend.

Workaround: None.

Checking for hardware compatibility in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the validation report generation task could take up to 30 minutes to finish or may appear to hang. The completion time depends on the number of devices configured on each host and the number of hosts configured in the cluster.

Workaround: None

Incomplete error messages in non-English languages are displayed, when remediating a cluster in vSphere Lifecycle Manager

You can encounter incomplete error messages for localized languages in the vCenter Server user interface. The messages are displayed, after a cluster remediation process in vSphere Lifecycle Manager fails. For example, your can observe the following error message.

The error message in English language: `Virtual machine 'VMC on DELL EMC -FileServer' that runs on cluster 'Cluster-1' reported an issue which prevents entering maintenance mode: Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

The error message in French language: `La VM « VMC on DELL EMC -FileServer », située sur le cluster « {Cluster-1} », a signalé un problème empêchant le passage en mode de maintenance : Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

Workaround: None.

When you convert a cluster that uses baselines to a cluster that uses a single image, a warning is displayed that vSphere HA VIBs will be removed

Converting a vSphere HA enabled cluster that uses baselines to a cluster that uses a single image, may result a warning message displaying that `vmware-fdm` component will be removed.

Workaround: This message can be ignored. The conversion process installs the `vmware-fdm` component.

If vSphere Update Manager is configured to download patch updates from the Internet through a proxy server, after upgrade to vSphere 7.0 that converts Update Manager to vSphere Lifecycle Manager, downloading patches from VMware patch repository might fail

In earlier releases of vCenter Server you could configure independent proxy settings for vCenter Server and vSphere Update Manager. After an upgrade to vSphere 7.0, vSphere Update Manager service becomes part of the vSphere Lifecycle Manager service. For the vSphere Lifecycle Manager service, the proxy settings are configured from the vCenter Server appliance settings. If you had configured Update Manager to download patch updates from the Internet through a proxy server but the vCenter Server appliance had no proxy setting configuration, after a vCenter Server upgrade to version 7.0, the vSphere Lifecycle Manager fails to connect to the VMware depot and is unable to download patches or updates.

Workaround: Log in to the vCenter Server Appliance Management Interface, https://*vcenter-server-appliance-FQDN-or-IP-address*:5480, to configure proxy settings for the vCenter Server appliance and enable vSphere Lifecycle Manager to use proxy.

If you use a Java client to review remediation tasks, you cannot extract the results from the remediation operations

If you use a Java client to review remediation tasks, extracting the results might fail with a `ConstraintValidationException` error. The issue occurs when an ESXi host fails to enter maintenance mode during the remediation and gets a status SKIPPED, but at the same time wrongly gets an In Progress flag for the consecutive remediation operations. This causes the `ConstraintValidationException` error on the Java Clients and you cannot extract the result of the remediation operation.

Workaround: Fix the underlying issues that prevent ESXi hosts to enter Maintenance Mode and retry the remediation operation.

The general vSphere Lifecycle Manager depot and local depots in Remote Office and Branch Office (ROBO) deployments might not be in sync

ROBO clusters that have limited or no access to the Internet or limited connectivity to vCenter Server can download an image from a depot that is local for them instead of accessing the vSphere Lifecycle Manager depot in vCenter Server. However, vSphere Lifecycle Manager generates software recommendations in the form of pre-validated images only on a central level and a recommended image content might not be available at a depot override.

Workaround: If you decide to use a recommended image, make sure the content between depot overrides and the central depot are in sync.

Cluster remediation by using the vSphere Lifecycle Manager might fail on ESXi hosts with enabled lockdown mode

If a cluster has ESXi hosts with enabled lockdown mode, remediation operations by using the vSphere Lifecycle Manager might skip such hosts. In the log files, you see messages such as `Host scan task failed` and `com.vmware.vcIntegrity.lifecycle.EsxImage.UnknownError An unknown error occurred while performing the operation..`

Workaround: Add the root user to the exception list for lockdown mode and retry the cluster remediation.

You cannot use an ESXi image with OEM content to create clusters by using vSphere Lifecycle Manager workflows after an update

When you update an ESXi image with OEM content, for example Dell ESXi 7.0 Update 2a to Dell ESXi 7.0 Update 3d, some reserved VIBs, such that are present in the VMware base image but overridden by async VIBs packaged by the OEM, might be deleted. The same issue might occur after updating your system by using a non-critical baseline and then update to a higher version by using an ESXi image with OEM content. For example, if you update to 7.0 Update 2 by using a non-critical baseline and then update to 7.0 Update 3 by using a Dell ESXi 7.0 Update 3 image, reserved VIBs might also be deleted. As a result, you cannot use ESXi hosts with the updated version to create a vSphere Lifecycle Manager cluster managed by a single image. The operation fails and in the backtrace, you see errors such as:

```
2021-11-24T09:42:49Z lifecycle: 2101166: HostSeeding:956 ERROR Extract depot failed:
('VMW_bootbank_bnxtroce_216.0.58.0-23vmw.703.0.0.18644231', 'Failed to add reserved

found in the reserved VIB cache storage')
```

Workaround: Use interactive or scripted upgrade instead of vSphere Lifecycle Manager workflows.

After you upgrade to vCenter Server 7.0.0b, in the vSphere Lifecycle Manager home view in the vSphere Client, you do not see the Show only rollup updates toggle button

In vCenter Server 7.0.0b, you can use the **Show only rollup updates** toggle button to filter and select patches that you want to include in a baseline when you use the vSphere Lifecycle Manager.

The button is available in the **Updates** tab on the **Lifecycle Manager** pane, **Menu** > **Lifecycle Manager**, which is the vSphere Lifecycle Manager home view in the vSphere Client. The button is also available in the **Select Patches Manually** page on the **Baselines** tab in the **Create Baseline** wizard, which opens when you select **New** > **Baseline**.

However, the **Show only rollup updates** toggle button might not be visible after you upgrade to vCenter Server 7.0.0b.

Workaround: After an upgrade to vCenter Server 7.0.0b, restart the vSphere Client. For more information, see Start, Stop, and Restart Services.

The Show only rollup updates toggle button is always turned on when you open a tab in the vSphere Lifecycle Manager home view in the vSphere Client

In vCenter Server 7.0.0b, you can use the **Show only rollup updates** toggle button to filter and select patches that you want to include in a baseline when you use the vSphere Lifecycle Manager.

The button is available in the **Updates** tab on the **Lifecycle Manager** pane, **Menu** > **Lifecycle Manager**, which is the vSphere Lifecycle Manager home view in the vSphere Client. The button is also available in the **Select Patches Manually** page on the **Baselines** tab in the **Create Baseline** wizard, which opens when you select **New** > **Baseline**.

However, the toggle button appears always turned on when you navigate to either of the **Updates** tab or the **Select Patches Manually** page. Even if you turn off the button when navigating away from the tab or page, it appears still turned on the next time you open them.

Workaround: None

When you use the Update Planner, in the vSphere Client you might see Unexpected error occurred while fetching the updates

When you use Update Planner, which is part of vSphere Lifecycle Manager, used to facilitate vCenter Server updates, you might see the following error in the vSphere Client:

```
Unexpected error occurred while fetching the updates
```

The issue occurs when you use a custom HTTPS port that prevents you from running interoperability reports by using the vSphere Client.

Workaround: Manually invoke the API. For more details, see the vSphere Automation API.

Miscellaneous Issues

When applying a host profile with version 6.5 to a ESXi host with version 7.0, the compliance check fails

Applying a host profile with version 6.5 to a ESXi host with version 7.0, results in Coredump file profile reported as not compliant with the host.

Workaround: There are two possible workarounds.

1. When you create a host profile with version 6.5, set an advanced configuration option VMkernel.Boot.autoCreateDumpFile to false on the ESXi host.
2. When you apply an existing host profile with version 6.5, add an advanced configuration option VMkernel.Boot.autoCreateDumpFile in the host profile, configure the option to a fixed policy, and set value to false.

Cannot migrate container volume due to insufficient space

The Migrate volume dialog in vSphere Client considers the current size of container volumes and the free space available on the target datastores. If the free space of a datastore is less than the volume size, then you cannot select the datastore for migration. vSphere preserves the storage policy as it migrates the volume, but the file size of the volume might change depending on the destination datastore type and its supported features. The vSphere Client might show the datastore has insufficient space to perform the migration, even though enough space is available.

Workaround: None

The Actions drop-down menu does not contain any items when your browser is set to language different from English

When your browser is set to language different from English and you click the **Switch to New View** button from the virtual machine **Summary** tab of the vSphere Client inventory, the **Actions** drop-down menu in the **Guest OS** panel does not contain any items.

Workaround: Select the **Actions** drop-down menu on the top of the virtual machine page.

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit minor throughput degradation when Dynamic Receive Side Scaling (DYN_RSS) or Generic RSS (GEN_RSS) feature is turned on

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit less than 5 percent throughput degradation when DYN_RSS and GEN_RSS feature is turned on, which is unlikely to impact normal workloads.

Workaround: You can deactivate DYN_RSS and GEN_RSS feature with the following commands:

```
# esxcli system module parameters set -m nmlx5_core -p "DYN_RSS=0 GEN_RSS=0"
# reboot
```

RDMA traffic between two VMs on the same host might fail in PVRDMA environment

In a vSphere 7.0 implementation of a PVRDMA environment, VMs pass traffic through the HCA for local communication if an HCA is present. However, loopback of RDMA traffic does not work on qedrntv driver. For instance, RDMA Queue Pairs running on VMs that are configured under same uplink port cannot communicate with each other.

In vSphere 6.7 and earlier, HCA was used for local RDMA traffic if SRQ was enabled. vSphere 7.0 uses HCA loopback with VMs using versions of PVRDMA that have SRQ enabled with a minimum of HW v14 using RoCE v2.

The current version of Marvell FastLinQ adapter firmware does not support loopback traffic between QPs of the same PF or port.

Workaround: Required support is being added in the out-of-box driver certified for vSphere 7.0. If you are using the inbox qedrntv driver, you must use a 3-host configuration and migrate VMs to the third host.

Unreliable Datagram traffic QP limitations in qedrntv driver

There are limitations with the Marvell FastLinQ qedrntv RoCE driver and Unreliable Datagram (UD) traffic. UD applications involving bulk traffic might fail with qedrntv driver. Additionally, UD QPs can only work with DMA Memory Regions (MR). Physical MRs or FRMR are not supported. Applications attempting to use physical MR or FRMR along with UD QP fail to pass traffic when used with qedrntv driver. Known examples of such test applications are `ibv_ud_pingpong` and `ib_send_bw`.

Standard RoCE and RoCEv2 use cases in a VMware ESXi environment such as iSER, NVMe-oF (RoCE) and PVRDMA are not impacted by this issue. Use cases for UD traffic are limited and this issue impacts a small set of applications requiring bulk UD traffic.

Marvell FastLinQ hardware does not support RDMA UD traffic offload. In order to meet the VMware PVRDMA requirement to support GSI QP, a restricted software only implementation of UD QP support was added to the qedrntv driver. The goal of the implementation is to provide support for control path GSI communication and is not a complete implementation of UD QP supporting bulk traffic and advanced features.

Since UD support is implemented in software, the implementation might not keep up with heavy traffic and packets might be dropped. This can result in failures with bulk UD traffic.

Workaround: Bulk UD QP traffic is not supported with qedrntv driver and there is no workaround at this time. VMware ESXi RDMA (RoCE) use cases like iSER, NVMe, RDMA and PVRDMA are unaffected by this issue.

Servers equipped with QLogic 578xx NIC might fail when frequently connecting or disconnecting iSCSI LUNs

If you trigger QLogic 578xx NIC iSCSI connection or disconnection frequently in a short time, the server might fail due to an issue with the qfle3 driver. This is caused by a known defect in the device's firmware.

Workaround: None.

ESXi might fail during driver unload or controller disconnect operation in Broadcom NVMe over FC environment

In Broadcom NVMe over FC environment, ESXi might fail during driver unload or controller disconnect operation and display an error message such as: `@BlueScreen: #PF Exception 14 in world 2098707:vmknvmeGener IP 0x4200225021cc addr 0x19`

Workaround: None.

ESXi does not display OEM firmware version number of i350/X550 NICs on some Dell servers

The inbox ixgben driver only recognizes firmware data version or signature for i350/X550 NICs. On some Dell servers the OEM firmware version number is programmed into the OEM package version region, and the inbox ixgben driver does not read this information. Only the 8-digit firmware signature is displayed.

Workaround: To display the OEM firmware version number, install async ixgben driver version 1.7.15 or later.

X710 or XL710 NICs might fail in ESXi

When you initiate certain destructive operations to X710 or XL710 NICs, such as resetting the NIC or manipulating VMKernel's internal device tree, the NIC hardware might read data from non-packet memory.

Workaround: Do not reset the NIC or manipulate vmkernel internal device state.

NVMe-oF does not guarantee persistent VMHBA name after system reboot

NVMe-oF is a new feature in vSphere 7.0. If your server has a USB storage installation that uses vmhba30+ and also has NVMe over RDMA configuration, the VMHBA name might change after a system reboot. This is because the VMHBA name assignment for NVMe over RDMA is different from PCIe devices. ESXi does not guarantee persistence.

Workaround: None.

Backup fails for vCenter database size of 300 GB or greater

If the vCenter database size is 300 GB or greater, the file-based backup will fail with a timeout. The following error message is displayed: `Timeout! Failed to complete in 72000 seconds`

Workaround: None.

A restore of vCenter Server 7.0 which is upgraded from vCenter Server 6.x with External Platform Services Controller to vCenter Server 7.0 might fail

When you restore a vCenter Server 7.0 which is upgraded from 6.x with External Platform Services Controller to vCenter Server 7.0, the restore might fail and display the following error: `Failed to retrieve appliance storage list`

Workaround: During the first stage of the restore process, increase the storage level of the vCenter Server 7.0. For example if the vCenter Server 6.7 External Platform Services Controller setup storage type is small, select storage type large for the restore process.

Enabled SSL protocols configuration parameter is not configured during a host profile remediation process

`Enabled SSL protocols` configuration parameter is not configured during a host profile remediation and only the system default protocol `tlsv1.2` is enabled. This behavior is observed for a host profile with version 7.0 and earlier in a vCenter Server 7.0 environment.

Workaround: To enable TLSV 1.0 or TLSV 1.1 SSL protocols for SFCB, log in to an ESXi host by using SSH, and run the following ESXCLI command: `esxcli system wbem -P <protocol_name>`

Unable to configure Lockdown Mode settings by using Host Profiles

Lockdown Mode cannot be configured by using a security host profile and cannot be applied to multiple ESXi hosts at once. You must manually configure each host.

Workaround: In vCenter Server 7.0, you can configure Lockdown Mode and manage Lockdown Mode exception user list by using a security host profile.

When a host profile is applied to a cluster, Enhanced vMotion Compatibility (EVC) settings are missing from the ESXi hosts

Some settings in the VMware config file `/etc/vmware/config` are not managed by Host Profiles and are blocked, when the config file is modified. As a result, when the host profile is applied to a cluster, the EVC settings are lost, which causes loss of EVC functionalities. For example, unmasked CPUs can be exposed to workloads.

Workaround: Reconfigure the relevant EVC baseline on cluster to recover the EVC settings.

Using a host profile that defines a core dump partition in vCenter Server 7.0 results in an error

In vCenter Server 7.0, configuring and managing a core dump partition in a host profile is not available. Attempting to apply a host profile that defines a core dump partition, results in the following error: `No valid coredump partition found.`

Workaround: None. In vCenter Server 7.0., Host Profiles supports only file-based core dumps.

You cannot paste by right clicking in the vi editor

If you use the vi text editor on a vCenter Server Appliance instance, you cannot paste previously copied content by right clicking. Instead, the vi editor changes mode to Visual.

Workaround: From the vCenter Server Appliance shell, run the command`/usr/bin/sed -i.bak -E '2alet skip_defaults_vim=1' /etc/vimrc`.

HTTP requests from certain libraries to vSphere might be rejected

The HTTP reverse proxy in vSphere 7.0 enforces stricter standard compliance than in previous releases. This might expose pre-existing problems in some third-party libraries used by applications for SOAP calls to vSphere.

If you develop vSphere applications that use such libraries or include applications that rely on such libraries in your vSphere stack, you might experience connection issues when these libraries send HTTP requests to VMOMI. For example, HTTP requests issued from vijava libraries can take the following form:

```
POST /sdk HTTP/1.1
SOAPAction
Content-Type: text/xml; charset=utf-8
User-Agent: Java/1.8.0_221
```

The syntax in this example violates an HTTP protocol header field requirement that mandates a colon after SOAPAction. Hence, the request is rejected in flight.

Workaround: Developers leveraging noncompliant libraries in their applications can consider using a library that follows HTTP standards instead. For example, developers who use the vijava library can consider using the latest version of the yavijava library instead.

SNMP dynamic firewall ruleset is modified by Host Profiles during a remediation process

The SNMP firewall ruleset is a dynamic state, which is handled during runtime. When a host profile is applied, the configuration of the ruleset is managed simultaneously by Host Profiles and SNMP, which can modify the firewall settings unexpectedly.

Workaround: There are two possible workarounds.

- To allow the ruleset to manage itself dynamically, exclude the SNMP firewall ruleset option in the configuration of the host profile.
- To proceed with the double management of the ruleset, when needed, correct the firewall ruleset state.

You might see a dump file when using Broadcom driver lsi_msgpt3, lsi_msgpt35 and lsi_mr3

When using the lsi_msgpt3, lsi_msgpt35 and lsi_mr3 controllers, there is a potential risk to see dump file lsuv2-lsi-drivers-plugin-util-zdump. There is an issue when exiting the storelib used in this plugin utility. There is no impact on ESXi operations, you can ignore the dump file.

Workaround: You can safely ignore this message. You can remove the lsuv2-lsi-drivers-plugin with the following command:

```
esxcli software vib remove -n lsuv2-lsiv2-drivers-plugin
```

You might see reboot is not required after configuring SR-IOV of a PCI device in vCenter, but device configurations made by third party extensions might be lost and require reboot to be re-applied.

In ESXi 7.0, SR-IOV configuration is applied without a reboot and the device driver is reloaded. ESXi hosts might have third party extensions perform device configurations that need to run after the device driver is loaded during boot. A reboot is required for those third party extensions to re-apply the device configuration.

Workaround: You must reboot after configuring SR-IOV to apply third party device configurations.

You see black or grey zones in the background of a parent window in the Direct Console User Interface (DCUI) after a child window closes

In the DCUI, when you close a child window by pressing the ESC or Enter keys, or the **Cancel** or **OK** buttons, the parent window appearance might change. The background color changes to grey or black for some part of the parent window. However, all required information from the DCUI is properly displayed and all operations performed in the DCUI complete successfully.

Workaround: Wait for 1 minute without refreshing the current window in the DCUI or pressing any key.

Backup Issues

If you use the NFS and SMB protocols for file-based backup of vCenter Server, the backup fails after an update from vCenter Server 7.x to vCenter Server 7.0 Update 1

If you use the Network File System (NFS) and Server Message Block (SMB) protocols for file-based backup of vCenter Server, the backup fails after an update from an earlier version of vCenter Server 7.x to vCenter Server 7.0 Update 1. In the `applmgmt.log` , you see an error message such as `Failed to mount the remote storage` . The issue occurs because of Linux kernel updates that run during the patch process. The issue does not occur on fresh installations of vCenter Server 7.0 Update 1.

Workaround: Reboot the vCenter Server appliance after the update is complete.

Microsoft Active Directory Federation Services (ADFS) logins might fail after restoring a vCenter Server Appliance

If you manually add a certificate to the vCenter Server JRE truststore or modify the `/etc/hosts` file when setting up ADFS, the changes are not preserved after restoring and might cause ADFS logins to fail.

Workaround: Add the ADFS certificate to the vCenter Server JRE truststore after restoring your vCenter Server Appliance. For more information, see Import the Trusted Certificate of an External Identity Provider. Add the necessary host name mappings back to the `/etc/hosts` file after restoring your vCenter Server Appliance.

vSAN Issues

Higher than actual vSAN storage pool free space estimate might lead to unexpected storage shortages

The `freeSpace` parameter of a vSAN storage pool might not exclude disks with errors and display the unused space estimate as higher than the actual. As a result, you might see unexpected storage shortages. This issue only affects vSAN storage pools.

Workaround: Manually compute the storage capacity by disregarding the `freeSpace` value of disks with errors from the overall storage capacity provided by the `freeSpace` parameter of the storage pool.

Server Configuration Issues

You see a message Error retrieving when trying to view the status of Key Management Server (KMS) instances in the vSphere Client

In the vSphere Client, you might see a message `Error retrieving` for several minutes when trying to view Key Management Server (KMS) instances. The issue occurs when a KMS instance in a standard key provider loses connectivity. Until all network requests to the affected KMS time out, which takes around 4 minutes, you cannot see the status of any KMS instance in your system, only the error message for the key provider. After the timeout, you can see the status of all KMS instances.

Workaround: If you see the Error retrieving message, wait for 4 minutes.

Due to a default timeout setting of 2 minutes, log in to vCenter instances in Enhanced Linked Mode takes long when any of the vCenters is down

When you have a number of vCenter instances in Enhanced Linked Mode, if one of the instances is down for some reason, such as maintenance, log in to the other instances might take up to 2 minutes, which is the default timeout setting. Changing the timeout property that specifies the wait time for log in to linked vCenter instances is a complex task that requires manually editing the `LinkedVcGroup.login.timeout` property located in `vim-commons-vsphere.properties` . To simlify the task, starting with vCenter Server 7.0 Update 3l, the setting `LinkedVcGroup.login.timeout=120000` moves from `vim-commons-vsphere.properties` to the `webclient.properties` file. Editing this option allows you to reduce the wait time so that if one of the vCenter logins is taking more time, it does not affect the log in time for other instances.

Workaround: Edit `/etc/vmware/vsphere-ui/webclient.properties` and change the value of `LinkedVcGroup.login.timeout` from `120000` to a smaller value in milliseconds, but consider that a value of `<= 0` is an infinite timeout.

vCenter Server Update and Patch Releases

VMware vCenter Server 7.0 Update 3w Release Notes

This document contains the following sections

- Introduction
- What's New
- Patches Contained in This Release
- Resolved Issues
- Known Issues from Prior Releases

Introduction

VMware vCenter Server 7.0 Update 3w | 29 SEP 2025 | ISO Build 24927011

Check for additions and updates to these release notes.

What's New

- This release resolves CVE-2025-41250. For more information on this vulnerability and its impact on Broadcom products, see VMSA-2025-0016.

Patches Contained in This Release

Patch for VMware vCenter 7.0 Update 3w

Download Filename	VMware-vCenter-Server-Appliance-7.0.3.02500-24927011-patch-FP.iso
Build	24927011
Download Size	6.23 GB
md5sum	0c9673c05cc9a92b80e4c4d3083f3979
sha256checksum	a1271853908a96d881e5e36fc70d2c1cc809b21fe3be38db29016588fdd9097c
PRs fixed	N/A
CVEs	CVE-2025-41250

Download and Installation

Log in to the Broadcom Support Portal to download this patch.

For download instructions for earlier releases, see Download Broadcom products and software.

For more information on using the vCenter Server shells, see VMware knowledge base article 2100508.

For more information on patching vCenter Server, see Patching the vCenter Server Appliance.

For more information on staging patches, see Stage Patches to vCenter Server Appliance.

For more information on installing patches, see Install vCenter Server Appliance Patches.

For more information on patching using the Appliance Management Interface, see Patching the vCenter Server by Using the Appliance Management Interface.

Resolved Issues

Security Issues

- This release resolves CVE-2025-41250. For more information on this vulnerability and its impact on Broadcom products, see VMSA-2025-0016.

Known Issues from Prior Releases

vSphere Cluster Services Issues

If all vSphere Cluster Service agent virtual machines in a cluster are down, vSphere DRS does not function in the cluster

If vSphere Cluster Service agent virtual machines fail to deploy or power on in a cluster, services such as vSphere DRS might be impacted.

Workaround: For more information on the issue and workarounds, see VMware knowledge base article 79892.

System virtual machines that support vSphere Cluster Services might impact cluster and datastore maintenance workflows

In vCenter Server 7.0 Update 1, vSphere Cluster Services adds a set of system virtual machines in every vSphere cluster to ensure the healthy operation of vSphere DRS. The system virtual machines deploy automatically with an implicit datastore selection logic. Depending on your cluster configuration, the system virtual machines might impact some of the cluster and datastore maintenance workflows.

Workaround: For more information on the impacted workflows and possible workarounds, see VMware knowledge base articles 79892 and 80483.

Installation, Upgrade, and Migration Issues

Upgrade to vSphere 7.0 Update 3c might require additional steps to force a full host-sync

The supported upgrade sequence for vSphere systems is first to upgrade vCenter Server and then ESXi. However, in certain environments with ESXi hosts of version 7.0 Update 2d and later, you need to update ESXi first to 7.0 Update 3c and then vCenter Server. Such an upgrade sequence requires additional steps to force a full host-sync.

Workaround: Log in to the appliance shell as a user with super administrative privileges (for example, `root`) and follow these steps:

1. Stop the vpxd service.
2. Run the command `/opt/vmware/vpostgres/current/bin/psql -U postgres -d VCDB -c "update VPX_HOST_SYNC_GEN set master_gen=0 where host_id in (select id from VPX_HOST where product_version like '7.0.3%')"`.
3. Start the vpxd service.

Patching vCenter to version 7.0 Update 3q might fail due to unsupported TLS ciphers in the Envoy proxy configuration

During the update of a vCenter instance to version 7.0 Update 3q, some services might fail to start due to custom configuration of the TLS cipher suites in the file `/etc/vmware-rhttpproxy/config.xml` . As a result, in the vSphere Client you see a warning such as `An error occurred while starting service 'vpxd-svcs'` and the process fails. If you use the Virtual Appliance Management Interface, you see an error such as `Installation Failed - Exception occurred in postInstallHook.`

Workaround: See KB 369485 for steps how to reset the TLS ciphers to their defaults and retry the vCenter update.

Hot-patched ESXi hosts with both i40en and i40enu Intel network drivers installed might fail to configure vSphere High Availability after upgrade to vCenter Server 7.0 Update 3c

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3c adds an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. However, if you apply an ESXi hot patch that is released after vCenter Server 7.0 Update 3c and then upgrade your system to vCenter Server 7.0 Update 3c, the hot patch might not be listed in the precheck. As a result, you might not follow the proper steps to the upgrade and vSphere HA might fail to configure on such hosts.

Workaround: Upgrade the hot-patched ESXi hosts to version 7.0 Update 3c.

The vCenter Upgrade/Migration pre-checks fail with "Unexpected error 87"

The vCenter Server Upgrade/Migration pre-checks fail when the Security Token Service (STS) certificate does not contain a Subject Alternative Name (SAN) field. This situation occurs when you have replaced the vCenter 5.5 Single Sign-On

certificate with a custom certificate that has no SAN field, and you attempt to upgrade to vCenter Server 7.0. The upgrade considers the STS certificate invalid and the pre-checks prevent the upgrade process from continuing.

Workaround: Replace the STS certificate with a valid certificate that contains a SAN field then proceed with the vCenter Server 7.0 Upgrade/Migration.

Problems upgrading to vSphere 7.0 with pre-existing CIM providers

After upgrade, previously installed 32-bit CIM providers stop working because ESXi requires 64-bit CIM providers. Customers may lose management API functions related to CIMPDK, NDDK (native DDK), HEXDK, VAIODK (IO filters), and see errors related to **uwglibc** dependency.

The syslog reports module missing, "32 bit shared libraries not loaded."

Workaround: There is no workaround. The fix is to download new 64-bit CIM providers from your vendor.

Patching to vCenter Server 7.0 Update 1 from earlier versions of vCenter Server 7.x is blocked when vCenter Server High Availability is enabled

Patching to vCenter Server 7.0 Update 1 from earlier versions of vCenter Server 7.x is blocked when vCenter Server High Availability is active.

Workaround: To patch your system to vCenter Server 7.0 Update 1 from earlier versions of vCenter Server 7.x, you must remove vCenter Server High Availability and delete the passive and witness nodes. After the upgrade, you must re-create your vCenter Server High Availability clusters.

Migration of a 6.7.x vCenter Server system to vCenter Server 7.x fails with an UnicodeEncodeError

If you select the option to import all data for configuration, inventory, tasks, events, and performance metrics, the migration of a 6.7.x vCenter Server system to vCenter Server 7.x might fail for any vCenter Server system that uses a non-English locale. At step 1 of stage 2 of the migration, in the vSphere Client, you see an error such as:

```
Error while exporting events and tasks data: …ERROR UnicodeEncodeError: Traceback (most recent call last):
```

Workaround: You can complete the migration operation by doing either:

- Select the default option **Configuration and Inventory** at the end of stage 1 of the migration. This option does not include tasks and events data.
- Clean the data in the events tables and run the migration again.

If a Windows vCenter Server system has a database password containing non-ASCII characters, pre-checks of the VMware Migration Assistant fail

If you try to migrate a 6.x vCenter Server system to vCenter Server 7.x by using the VMware Migration Assistant, and your system has a Windows OS, and uses an external database with a password containing non-ASCII characters, the operation fails. For example, Admin!23迁移. In the Migration Assistant console, you see the following error:

```
Error:Component com.vmware.vcdb failed with internal errorResolution:File Bugzilla PR to VPX/VPX/vcdb-upgrade
```

Workaround: None

During an update from vCenter Server 7.x to vCenter Server 7.0 Update 1, you get prompts to provide the vCenter Single Sign-On password

During an update from vCenter Server 7.x to vCenter Server 7.0 Update 1, you get prompts to provide vCenter Single Sign-On administrator password.

Workaround: If you run the update by using the vCenter Server Management Interface, you must provide the vCenter Single Sign-On administrator password.

If you run the update by using software-packages or CLI in an interactive manner, you must interactively provide the vCenter Single Sign-On administrator password.

If you run the update by using software-packages or CLI in a non-interactive manner, you must provide the vCenter Single Sign-On administrator password by an answer file in the format

```
{ "vmdir.password": "SSO Password of Administrator@<SSO-DOMAIN> user" }
```

Smart Card and RSA SecurID authentication might stop working after upgrading to vCenter Server 7.0

If you have configured vCenter Server for either Smart Card or RSA SecurID authentication, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057 before starting the vSphere 7.0 upgrade process. If you do not perform the workaround as described in the KB, you might see the following error messages and Smart Card or RSA SecurID authentication does not work.

"Smart card authentication may stop working. Smart card settings may not be preserved, and smart card authentication may stop working."

or

"RSA SecurID authentication may stop working. RSA SecurID settings may not be preserved, and RSA SecurID authentication may stop working."

Workaround: Before upgrading to vSphere 7.0, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057.

You might not be able to apply or remove NSX while you add ESXi hosts by using a vSphere Lifecycle Manager image to a cluster with enabled VMware vSphere High Availability

If you start an operation to apply or remove NSX while adding multiple ESXi hosts by using a vSphere Lifecycle Manager image to a vSphere HA-enabled cluster, the NSX-related operations might fail with an error in the vSphere Client such as:

```
vSphere HA agent on some of the hosts on cluster <cluster_name> is neither vSphere HA master agent nor connected to vSphere HA master agent. Verify that the HA configuration is correct.
```

The issue occurs because vSphere Lifecycle Manager configures vSphere HA for the ESXi hosts being added to the cluster one at a time. If you run an operation to apply or remove NSX while vSphere HA configure operations are still in progress, NSX operations might queue up between the vSphere HA configure operations for two different ESXi hosts. In such a case, the NSX operation fails with a cluster health check error, because the state of the cluster at that point does not match the expected state that all ESXi hosts have vSphere HA configured and running. The more ESXi hosts you add to a cluster at the same time, the more likely the issue is to occur.

Workaround: Deactivate and enable Sphere HA on the cluster. Proceed with the operations to apply or remove NSX.

After an upgrade of a vCenter Server 7.0 system, you cannot see the IP addresses of pods in the vSphere Pod Summary tab of the vSphere Client

If you upgrade your vCenter Server 7.0 system to a later version, you can no longer see the IP addresses of pods in the **vSphere Pod Summary** tab of the vSphere Client.

Workaround: Use the Kubernetes CLI Tools for vSphere to review details of pods:

1. As a prerequisite, copy the pod and namespace names.
   - In the vSphere Client, navigate to **Workload Management** > **Clusters.**

- Copy the IP displayed in the **Control Plane Node IP Address** tab.
- You can navigate to `https://<control_plane_node_IP_address>` and download the Kubernetes CLI Tools, `kubectl` and `kubectl-vsphere`.
  Alternatively, follow the steps in Download and Install the Kubernetes CLI Tools for vSphere.

2. Use the CLI plug-in for vSphere to review the pod details.
   a. Log in to the Supervisor cluster by using the command
      `kubectl vsphere login --server=https://<server_adress> --vsphere-username <your user account name> --insecure-skip-tls-verify`
   b. By using the names copied in step 1, run the commands for retrieving the pod details:
      `kubectl config use-context <namespace_name>`
      and
      `kubectl describe pod <pod_name> -n <namespace_name>`

As a result, you can see the IP address in an output similar to:

```
$ kubectl describe pod helloworld -n my-podvm-ns ...
Status: Running
IP: 10.0.0.10
IPs:
IP: 10.0.0.10 ...
```

Upgrading a vCenter Server with an external Platform Services Controller from 6.7u3 to 7.0 fails with VMAFD error

When you upgrade a vCenter Server deployment using an external Platform Services Controller, you converge the Platform Services Controller into a vCenter Server appliance. If the upgrade fails with the error `install.vmafd.vmdir_vdcpromo_error_21`, the VMAFD firstboot process has failed. The VMAFD firstboot process copies the VMware Directory Service Database (data.mdb) from the source Platform Services Controller and replication partner vCenter Server appliance.

Workaround: Deactivate TCP Segmentation Offload (TSO) and Generic Segmentation Offload (GSO) on the Ethernet adapter of the source Platform Services Controller or replication partner vCenter Server appliance before upgrading a vCenter Server with an external Platform Services Controller. See Knowledge Base article: https://kb.vmware.com/s/article/74678

vCenter Server system upgrades fail in the pre-check stage

Upgrades of your vCenter Server system might fail in the pre-check stage due to a limit in the authorization (Authz) connections. In the `/var/log/vmware/vpxd-svcs/vpxd-svcs*.log` file you see entries such as:

`Session count for user [after add]: <DOMAIN-NAME>\machine-xxxx is 200Session limit reached for user: <DOMAIN-NAME>\machine-xxxx with 200 sessions.`

You might also see delayed response from the vSphere Client to load the inventory.

Workaround: Restart vmware-vpxd-svcs in your vCenter Server system by using the command `service-control --restart vmware-vpxd-svcs`. Use the command only when no other activity runs in the vCenter Server system to avoid any interruptions to the workflow. For more information, see VMware knowledge base article 81953.

Upgrading vCenter Server using the CLI incorrectly preserves the Transport Security Layer (TLS) configuration for the vSphere Authentication Proxy service

If the vSphere Authentication Proxy service (`vmcam`) is configured to use a particular TLS protocol other than the default TLS 1.2 protocol, this configuration is preserved during the CLI upgrade process. By default, vSphere supports the TLS

1.2 encryption protocol. If you must use the TLS 1.0 and TLS 1.1 protocols to support products or services that do not support TLS 1.2, use the TLS Configurator Utility to enable or deactivate different TLS protocol versions.

Workaround: Use the TLS Configurator Utility to configure the `vmcam` port. To learn how to manage TLS protocol configuration and use the TLS Configurator Utility, see the *VMware Security* documentation.

You do not see a precheck error when patching to vCenter Server 7.0 Update 3c by using CLI

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3c adds an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. In some cases, if such hosts exist in your system, patching from an vCenter Server version earlier than 7.0 Update 3 to a version later than 7.0 Update 3 by using CLI might fail with the error `Installation failed. Retry to resume from the current state. Or please collect the VC support bundle.`.

However, instead of this error, you must see the precheck error message.

Workaround: If you do not see the precheck error and patching your system to vCenter Server 7.0 Update 3c fails, make sure all ESXi hosts are upgraded to ESXi 7.0 Update 3c or higher, by using either a baseline created from an ISO or a single image, before upgrading vCenter Server. Do not use patch baselines based on the rollup bulletin. You can find additional debug log information at `/var/log/vmware/applmgmt` . For more details, see VMware knowledge base articles 87319 and 86447.

Smart card and RSA SecurID settings may not be preserved during vCenter Server upgrade

Authentication using RSA SecurID will not work after upgrading to vCenter Server 7.0. An error message will alert you to this issue when attempting to login using your RSA SecurID login.

Workaround: Reconfigure the smart card or RSA SecureID.

Upgrade to vSphere 7.0 Update 3c might require additional steps to force a full host-sync

The supported upgrade sequence for vSphere systems is first to upgrade vCenter Server and then ESXi. However, in certain environments with ESXi hosts of version 7.0 Update 2c and later, you need to update ESXi first to 7.0 Update 3c and then vCenter Server. Such an upgrade sequence requires additional steps to force a full host-sync.

Workaround: Log in to the appliance shell as a user with super administrative privileges (for example, `root`) and follow these steps:

1. Stop the vpxd service.
2. Run the command `/opt/vmware/vpostgres/current/bin/psql -U postgres -d VCDB -c "update VPX_HOST_SYNC_GEN set master_gen=0 where host_id in (select id from VPX_HOST where product_version like '7.0.3%')"`.
3. Start the vpxd service.

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with network error message

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with the error message `IP already exists in the network`. This prevents the migration process from configuring the network parameters on the new vCenter Server appliance. For more information, examine the log file: `/var/log/vmware/upgrade/UpgradeRunner.log`

Workaround:

1. Verify that all Windows Updates have been completed on the source vCenter Server for Windows instance, or deactivate automatic Windows Updates until after the migration finishes.
2. Retry the migration of vCenter Server for Windows to vCenter Server appliance 7.0.

Hot-patched ESXi hosts with both i40en and i40enu Intel network drivers installed might fail to configure vSphere High Availability after upgrade to vCenter Server 7.0 Update 3c

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3c adds an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. However, if you apply an ESXi hot patch that is released after vCenter Server 7.0 Update 3c and then upgrade your system to vCenter Server 7.0 Update 3c, the hot patch might not be listed in the precheck. As a result, you might not follow the proper steps to the upgrade and vSphere HA might fail to configure on such hosts.

Workaround: Upgrade the hot-patched ESXi hosts to version 7.0 Update 3c.

When you configure the number of virtual functions for an SR-IOV device by using the max_vfs module parameter, the changes might not take effect

In vSphere 7.0, you can configure the number of virtual functions for an SR-IOV device by using the Virtual Infrastructure Management (VIM) API, for example, through the vSphere Client. The task does not require reboot of the ESXi host. After you use the VIM API configuration, if you try to configure the number of SR-IOV virtual functions by using the `max_vfs` module parameter, the changes might not take effect because they are overridden by the VIM API configuration.

Workaround: None. To configure the number of virtual functions for an SR-IOV device, use the same method every time. Use the VIM API or use the `max_vfs` module parameter and reboot the ESXi host.

Upgraded vCenter Server appliance instance does not retain all the secondary networks (NICs) from the source instance

During a major upgrade, if the source instance of the vCenter Server appliance is configured with multiple secondary networks other than the VCHA NIC, the target vCenter Server instance will not retain secondary networks other than the VCHA NIC. If the source instance is configured with multiple NICs that are part of VDS port groups, the NIC configuration will not be preserved during the upgrade. Configurations for vCenter Server appliance instances that are part of the standard port group will be preserved.

Workaround: None. Manually configure the secondary network in the target vCenter Server appliance instance.

After upgrading or migrating a vCenter Server with an external Platform Services Controller, users authenticating using Active Directory lose access to the newly upgraded vCenter Server instance

After upgrading or migrating a vCenter Server with an external Platform Services Controller, if the newly upgraded vCenter Server is not joined to an Active Directory domain, users authenticating using Active Directory will lose access to the vCenter Server instance.

Workaround: Verify that the new vCenter Server instance has been joined to an Active Directory domain. See Knowledge Base article: https://kb.vmware.com/s/article/2118543

Migrating a vCenter Server for Windows with an external Platform Services Controller using an Oracle database fails

If there are non-ASCII strings in the Oracle events and tasks table the migration can fail when exporting events and tasks data. The following error message is provided: UnicodeDecodeError

Workaround: None.

After an ESXi host upgrade, a Host Profile compliance check shows non-compliant status while host remediation tasks fail

The non-compliant status indicates an inconsistency between the profile and the host.

This inconsistency might occur because ESXi 7.0 does not allow duplicate claim rules, but the profile you use contains duplicate rules. For example, if you attempt to use the Host Profile that you extracted from the host before upgrading ESXi

6.5 or ESXi 6.7 to version 7.0 and the Host Profile contains any duplicate claim rules of system default rules, you might experience the problems.

Workaround:

1. Remove any duplicate claim rules of the system default rules from the Host Profile document.
2. Check the compliance status.
3. Remediate the host.
4. If the previous steps do not help, reboot the host.

Error message displays in the vCenter Server Management Interface

After installing or upgrading to vCenter Server 7.0, when you navigate to the Update panel within the vCenter Server Management Interface, the error message "Check the URL and try again" displays. The error message does not prevent you from using the functions within the Update panel, and you can view, stage, and install any available updates.

Workaround: None.

Patching witness or passive nodes of environments with VMware vCenter Server High Availability enabled might fail

In environments with vCenter Server High Availability enabled, patching a witness or passive node might fail with a message similar to:

`RuntimeError: unidentifiable C++ exception.`

Workaround: Deactivate vCenter Server High Availability. Apply patches to your vCenter Server system. Re-enable vCenter Server High Availability.

After patching your vCenter Server system to vCenter Server 7.0.0a, the TLS version of the VC Storage Clients might revert to the default

If you have a TLS configuration for the VC Storage Clients service different from the default TLS 1.2 only, the TLS version might revert to the default after patching your vCenter Server system to vCenter Server 7.0.0a.

Workaround: Use the TLS Configuration utility to enable or deactivate TLS versions on your vCenter Server system after the update.

After updating your system to vCenter Server 7.0.0b, you see systemd core dump in the /var/core folder

After updating your system to vCenter Server 7.0.0b from either vCenter Server 7.0.0a or vCenter Server 7.0, in the `/var/core` folder you see systemd core dump, such as `core.systemd-journal.393` and `core.systemd-udevd.405`. The core dump is harmless and can be removed.

Workaround: None

After updating your vCenter Server system to 7.0.0b, the vCenter Server version is not updated in the Direct Console User Interface (DCUI)

After updating your system to vCenter Server 7.0.0b from vCenter Server 7.0.0a or vCenter Server 7.0, you still see the previous vCenter Server version in the DCUI.

Workaround: After you complete the update, to refresh the vCenter Server version, in the appliance shell, run the command `/usr/lib/applmgmt/dcui/notify`.

Update Planner fails with error Configured repository is not accessible due to network connectivity or incorrect URL

If you use Update Planner, which is part of vSphere Lifecycle Manager used to facilitate vCenter Server updates, you might see the following error in the vSphere Client:

`Configured repository is not accessible due to network connectivity or incorrect URL. Verify the repository settings.`

The issue occurs when you use a custom local repository, such as `https:///uploads/dpe/` or a DBC path, to store the extracted . If the custom repository for URL-based patching has an authentication policy, Update Planner might not be able to fetch the list of available updates.

Workaround: Configure the custom repository such that authentication is not needed to access the custom repository URL.

After upgrading to vCenter Server 7.0.0b, you see vSphere HA errors on vSphere Lifecycle Manager Image based clusters

After upgrading to vCenter Server 7.0.0b, on vSphere Lifecycle Manager Image based clusters that are configured with vSphere HA, you might see error messages about the vSphere HA configuration after logging in for the first time to the environment. In the vSphere Client, you see messages such as:

`Cannot complete the configuration of the vSphere HA agent on the host.` or

`Applying HA VIBs on the cluster encountered a failure.`

The issue occurs because exports of the image depot might take long and cause a timeout of the task. In the `/storage/log/vmware/vmware-updatemgr/vum-server/vmware-vum-server.log` you see this message: `Export taking too long (Failure case)`

Workaround: This is a transient issue that resolves in 10 minutes after the vCenter Server is up and running. The issue does not affect any functionality. vSphere HA on the affected clusters operates as expected. All operations related to virtual machines, such as power on and migration, work across the vSphere HA-enabled clusters while this error recovery is still in progress.

You do not see a precheck error when patching to vCenter Server 7.0 Update 3d by using CLI

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3d and later add an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. In some cases, if such hosts exist in your system, patching from a vCenter Server version earlier than 7.0 Update 3 to a version later than 7.0 Update 3 by using CLI might fail with the error `Installation failed. Retry to resume from the current state. Or please collect the VC support bundle.` . However, instead of this error, you must see the precheck error message.

Workaround: If you do not see the precheck error and patching your system to vCenter Server 7.0 Update 3d fails, make sure all ESXi hosts are upgraded to ESXi 7.0 Update 3d, by using either a baseline created from an ISO or a single image, before upgrading vCenter Server. Do not use patch baselines based on the rollup bulletin. You can find additional debug log information at `/var/log/vmware/applmgmt` . For more details, see VMware knowledge base articles 87319 and 86447.

Security Features Issues

Encrypted virtual machine fails to power on when HA-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled HA on the Trusted Cluster and one or more hosts in the cluster fails attestation, an encrypted virtual machine cannot power on.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Encrypted virtual machine fails to power on when DRS-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled DRS on the Trusted Cluster and one or more hosts in the cluster fails attestation, DRS might try to power on an encrypted virtual machine on an unattested host in the cluster. This operation puts the virtual machine in a locked state.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Migrating or cloning encrypted virtual machines across vCenter Server instances fails when attempting to do so using the vSphere Client

If you try to migrate or clone an encrypted virtual machine across vCenter Server instances using the vSphere Client, the operation fails with the following error message: "The operation is not allowed in the current state."

Workaround: You must use the vSphere APIs to migrate or clone encrypted virtual machines across vCenter Server instances.

Networking Issues

PR3304411: After batch cloning and customizing Windows virtual machines, the VMs network might not be configured

When cloning Windows VMs in bulk, a MAC address conflict might occur, causing vCenter to reassign new MAC addresses to the VMs. As a result, the guest customization process fails to configure properly the VMs network because it cannot match the original MAC address to the corresponding network card.

This issue is resolved in this release.

When you use the VMware Remote Console, the envoy service might intermittently fail

An issue with the envoy service specific to the VMware Remote Console might lead to intermittent failures of the service. As a result, the vCenter Server Management Interface or vCenter Server APIs might also become unavailable.

Workaround: Use the vSphere Client as an alternative to the VMware Remote Console.

Reduced throughput in networking performance on Intel 82599/X540/X550 NICs

The new queue-pair feature added to ixgben driver to improve networking performance on Intel 82599EB/X540/X550 series NICs might reduce throughput under some workloads in vSphere 7.0 as compared to vSphere 6.7.

Workaround: To achieve the same networking performance as vSphere 6.7, you can deactivate the queue-pair with a module parameter. To deactivate the queue-pair, run the command:

```
# esxcli system module parameters set -p "QPair=0,0,0,0..." -m ixgben
```

After running the command, reboot.

If you try to deactivate vSphere with Tanzu on a vSphere cluster, the operation stops with an error

If some virtual machines outside of a Supervisor Cluster reside on any of the NSX segment port groups on the cluster, the cleanup script cannot delete such ports and deactivate vSphere with Tanzu on the cluster. In the vSphere Client, you see the error `Cleanup requests to NSX Manager failed` and the operation stops at `Removing` status. In the `/var/log/vmware/wcp/wcpsvc.log` file, you see an error message such as

```
Segment path=[...] has x VMs or VIFs attached. Disconnect all VMs and VIFs before deleting a segment.
```

Workaround: Delete the virtual machines indicated in the `/var/log/vmware/wcp/wcpsvc.log` file from the segment. Wait for the operation to restore.

After upgrading to NSX 6.4.7, when a static IPv6 address is assigned to workload VMs on an IPv6 network, the VMs are unable to ping the IPv6 gateway interface of the edge

This issue occurs after upgrading the vSphere Distributed Switches from 6.x to 7.0.

Workaround 1:

Select the VDS where all the hosts are connected, go to the **Edit** setting, and under **Multicast** option switch to basic.

Workaround 2:

Add the following rules on the edge firewall:

Ping allow rule.

Multicast Listener Discover (MLD) allow rule, which are icmp6, type 130 (v1) and type 143 (v2).

High throughput virtual machines may experience degradation in network performance when Network I/O Control (NetIOC) is enabled

Virtual machines requiring high network throughput can experience throughput degradation when upgrading from vSphere 6.7 to vSphere 7.0 with NetIOC enabled.

Workaround: Adjust the `ethernetx.ctxPerDev` setting to enable multiple worlds.

IPv6 traffic fails to pass through VMkernel ports using IPsec

When you migrate VMkernel ports from one port group to another, IPv6 traffic does not pass through VMkernel ports using IPsec.

Workaround: Remove the IPsec security association (SA) from the affected server, and then reapply the SA. To learn how to set and remove an IPsec SA, see the *vSphere Security* documentation.

Higher ESX network performance with a portion of CPU usage increase

ESX network performance may increase with a portion of CPU usage.

Workaround: Remove and add the network interface with only 1 rx dispatch queue. For example:

```
esxcli network ip interface remove --interface-name=vmk1
esxcli network ip interface add --interface-name=vmk1 --num-rxqueue=1
```

VM might lose Ethernet traffic after hot-add, hot-remove or storage vMotion

A VM might stop receiving Ethernet traffic after a hot-add, hot-remove or storage vMotion. This issue affects VMs where the uplink of the VNIC has SR-IOV enabled. PVRDMA virtual NIC exhibits this issue when the uplink of the virtual network is a Mellanox RDMA capable NIC and RDMA namespaces are configured.

Workaround: You can hot-remove and hot-add the affected Ethernet NICs of the VM to restore traffic. On Linux guest operating systems, restarting the network might also resolve the issue. If these workarounds have no effect, you can reboot the VM to restore network connectivity.

Change of IP address for a VCSA deployed with static IP address requires that you create the DNS records in advance

With the introduction of the DDNS, the DNS record update only works for VCSA deployed with DHCP configured networking. While changing the IP address of the vCenter server via VAMI, the following error is displayed:

The specified IP address does not resolve to the specified hostname.

Workaround: There are two possible workarounds.

1. Create an additional DNS entry with the same FQDN and desired IP address. Log in to the VAMI and follow the steps to change the IP address.

2. Log in to the VCSA using ssh. Execute the following script:
   `./opt/vmware/share/vami/vami_config_net`
   Use option 6 to change the IP adddress of eth0. Once changed, execute the following script:
   `./opt/likewise/bin/lw-update-dns`
   Restart all the services on the VCSA to update the IP information on the DNS server.

It may take several seconds for the NSX Distributed Virtual Port Group (NSX DVPG) to be removed after deleting the corresponding logical switch in NSX Manager.

As the number of logical switches increases, it may take more time for the NSX DVPG in vCenter Server to be removed after deleting the corresponding logical switch in NSX Manager. In an environment with 12000 logical switches, it takes approximately 10 seconds for an NSX DVPG to be deleted from vCenter Server.

Workaround: None.

Hostd runs out of memory and fails if a large number of NSX Distributed Virtual port groups are created.

In vSphere 7.0, NSX Distributed Virtual port groups consume significantly larger amounts of memory than opaque networks. For this reason, NSX Distributed Virtual port groups can not support the same scale as an opaque network given the same amount of memory.

Workaround:To support the use of NSX Distributed Virtual port groups, increase the amount of memory in your ESXi hosts. If you verify that your system has adequate memory to support your VMs, you can directly increase the memory of `hostd` using the following command.

```
localcli --plugin-dir /usr/lib/vmware/esxcli/int/ sched group setmemconfig --group-path
host/vim/vmvisor/hostd --units mb --min 2048 --max 2048
```

Note that this will cause `hostd` to use memory normally reserved for your environment's VMs. This may have the affect of reducing the number of VMs your ESXi host can support.

DRS may incorrectly launch vMotion if the network reservation is configured on a VM

If the network reservation is configured on a VM, it is expected that DRS only migrates the VM to a host that meets the specified requirements. In a cluster with NSX transport nodes, if some of the transport nodes join the transport zone by NSX-T Virtual Distributed Switch (N-VDS), and others by vSphere Distributed Switch (VDS) 7.0, DRS may incorrectly launch vMotion. You might encounter this issue when:

- The VM connects to an NSX logical switch configured with a network reservation.
- Some transport nodes join transport zone using N-VDS, and others by VDS 7.0, or, transport nodes join the transport zone through different VDS 7.0 instances.

Workaround: Make all transport nodes join the transport zone by N-VDS or the same VDS 7.0 instance.

When adding a VMkernel NIC (vmknic) to an NSX portgroup, vCenter Server reports the error "Connecting VMKernel adapter to a NSX Portgroup on a Stateless host is not a supported operation. Please use Distributed Port Group instead."

- For stateless ESXi on Distributed Virtual Switch (VDS), the vmknic on a NSX port group is blocked. You must instead use a Distributed Port Group.
- For stateful ESXi on VDS, vmknic on NSX port group is supported, but vSAN may have an issue if it is using vmknic on a NSX port group.

Workaround: Use a Distributed Port Group on the same VDS.

Enabling SRIOV from vCenter for QLogic 4x10GE QL41164HFCU CNA might fail

If you navigate to the **Edit Settings** dialog for physical network adapters and attempt to enable SR-IOV, the operation might fail when using QLogic 4x10GE QL41164HFCU CNA. Attempting to enable SR-IOV might lead to a network outage of the ESXi host.

Workaround: Use the following command on the ESXi host to enable SRIOV:

```
esxcfg-module
```

Storage Issues

VMFS datastores are not mounted automatically after disk hot remove and hot insert on HPE Gen10 servers with SmartPQI controllers

When SATA disks on HPE Gen10 servers with SmartPQI controllers without expanders are hot removed and hot inserted back to a different disk bay of the same machine, or when multiple disks are hot removed and hot inserted back in a different order, sometimes a new local name is assigned to the disk. The VMFS datastore on that disk appears as a snapshot and will not be mounted back automatically because the device name has changed.

Workaround: None. SmartPQI controller does not support unordered hot remove and hot insert operations.

ESXi might terminate I/O to NVMeOF devices due to errors on all active paths

Occasionally, all active paths to NVMeOF device register I/O errors due to link issues or controller state. If the status of one of the paths changes to Dead, the High Performance Plug-in (HPP) might not select another path if it shows high volume of errors. As a result, the I/O fails.

Workaround: Deactivate the configuration option **/Misc/HppManageDegradedPaths** to unblock the I/O.

VOMA check on NVMe based VMFS datastores fails with error

VOMA check is not supported for NVMe based VMFS datastores and will fail with the error:

```
ERROR: Failed to reserve device. Function not implemented
```

Example:

```
# voma -m vmfs -f check -d /vmfs/devices/disks/: <partition#>
Running VMFS Checker version 2.1 in check mode
Initializing LVM metadata, Basic Checks will be done

Checking for filesystem activity
Performing filesystem liveness check..|Scanning for VMFS-6 host activity (4096 bytes/HB, 1024 HBs).
ERROR: Failed to reserve device. Function not implemented
Aborting VMFS volume check
VOMA failed to check device : General Error
```

Workaround: None. If you need to analyse VMFS metadata, collect it using the `-l` option, and pass to VMware customer support. The command for collecting the dump is:

```
voma -l -f dump -d /vmfs/devices/disks/:<partition#>
```

Using the VM reconfigure API to attach an encrypted First Class Disk to an encrypted virtual machine might fail with error

If an FCD and a VM are encrypted with different crypto keys, your attempts to attach the encrypted FCD to the encrypted VM using the `VM reconfigure API` might fail with the error message:

```
Cannot decrypt disk because key or password is incorrect.
```

Workaround: Use the `attachDisk API` rather than the `VM reconfigure API` to attach an encrypted FCD to an encrypted VM.

ESXi host might get in non responding state if a non-head extent of its spanned VMFS datastore enters the Permanent Device Loss (PDL) state

This problem does not occur when a non-head extent of the spanned VMFS datastore fails along with the head extent. In this case, the entire datastore becomes inaccessible and no longer allows I/Os.

In contrast, when only a non-head extent fails, but the head extent remains accessible, the datastore heartbeat appears to be normal. And the I/Os between the host and the datastore continue. However, any I/Os that depend on the failed non-head extent start failing as well. Other I/O transactions might accumulate while waiting for the failing I/Os to resolve, and cause the host to enter the non responding state.

Workaround: Fix the PDL condition of the non-head extent to resolve this issue.

After recovering from APD or PDL conditions, VMFS datastore with enabled support for clustered virtual disks might remain inaccessible

You can encounter this problem only on datastores where the clustered virtual disk support is enabled. When the datastore recovers from an All Paths Down (APD) or Permanent Device Loss (PDL) condition, it remains inaccessible. The VMkernel log might show multiple `SCSI3 reservation conflict` messages similar to the following:

```
2020-02-18T07:41:10.273Z cpu22:1001391219)ScsiDeviceIO: vm 1001391219:
SCSIDeviceCmdCompleteCB:2972: Reservation conflict retries 544 for command 0x45ba814b8340
(op: 0x89) to device "naa.624a9370b97601e346f64ba900024d53"
```

The problem can occur because the ESXi host participating in the cluster loses SCSI reservations for the datastore and cannot always reacquire them automatically after the datastore recovers.

Workaround: Manually register the reservation using the following command:

```
vmkfstools -L registerkey /vmfs/devices/disks/<device name>
```

where the `<device name>` is the name of the device on which the datastore is created.

Virtual NVMe Controller is the default disk controller for Windows 10 guest operating systems

The Virtual NVMe Controller is the default disk controller for the following guest operating systems when using Hardware Version 15 or later:

Windows 10

Windows Server 2016

Windows Server 2019

Some features might not be available when using a Virtual NVMe Controller. For more information, see https://kb.vmware.com/s/article/2147714

Note: Some clients use the previous default of LSI Logic SAS. This includes ESXi host client and PowerCLI.

Workaround: If you need features not available on Virtual NVMe, switch to VMware Paravirtual SCSI (PVSCSI) or LSI Logic SAS. For information on using VMware Paravirtual SCSI (PVSCSI), see https://kb.vmware.com/s/article/1010398

After an ESXi host upgrade to vSphere 7.0, presence of duplicate core claim rules might cause unexpected behavior

Claim rules determine which multipathing plugin, such as NMP, HPP, and so on, owns paths to a particular storage device. ESXi 7.0 does not support duplicate claim rules. However, the ESXi 7.0 host does not alert you if you add duplicate rules

to the existing claim rules inherited through an upgrade from a legacy release. As a result of using duplicate rules, storage devices might be claimed by unintended plugins, which can cause unexpected outcome.

Workaround: Do not use duplicate core claim rules. Before adding a new claim rule, delete any existing matching claim rule.

A CNS query with the compliance status filter set might take unusually long time to complete

The CNS QueryVolume API enables you to obtain information about the CNS volumes, such as volume health and compliance status. When you check the compliance status of individual volumes, the results are obtained quickly. However, when you invoke the CNS QueryVolume API to check the compliance status of multiple volumes, several tens or hundreds, the query might perform slowly.

Workaround: Avoid using bulk queries. When you need to get compliance status, query one volume at a time or limit the number of volumes in the query API to 20 or fewer. While using the query, avoid running other CNS operations to get the best performance.

New Deleted CNS volumes might temporarily appear as existing in the CNS UI

After you delete an FCD disk that backs a CNS volume, the volume might still show up as existing in the CNS UI. However, your attempts to delete the volume fail. You might see an error message similar to the following:

```
The object or item referred to could not be found.
```

Workaround: The next full synchronization will resolve the inconsistency and correctly update the CNS UI.

New Under certain circumstances, while a CNS operation fails, the task status appears as successful in the vSphere Client

This might occur when, for example, you use an incompliant storage policy to create a CNS volume. The operation fails, while the vSphere Client shows the task status as successful.

Workaround: The successful task status in the vSphere Client does not guarantee that the CNS operation succeeded. To make sure the operation succeeded, verify its results.

New Unsuccessful delete operation for a CNS persistent volume might leave the volume undeleted on the vSphere datastore

This issue might occur when the CNS Delete API attempts to delete a persistent volume that is still attached to a pod. For example, when you delete the Kubernetes namespace where the pod runs. As a result, the volume gets cleared from CNS and the CNS query operation does not return the volume. However, the volume continues to reside on the datastore and cannot be deleted through the repeated CNS Delete API operations.

Workaround: None.

vCenter Server and vSphere Client Issues

PR 3262556: vCenter upgrade fails with "VP last sync time not updated after waiting for 5 minutes after vCenter update"

In rare cases, during a vCenter upgrade, a race condition between vSphere API for Storage Awareness (VASA) providers might cause the upgrade to fail. In the `pod-service.log` file, you see an error such as `vSAN VP last sync time not updated after waiting for 5 minutes after vCenter update.`

This issue is resolved in this release. The fix prevents the race condition.

You do not see the VLAN ID in the port properties page of a VMkernel network adapter in the vSphere Client

In the vSphere Client, when you follow the path **Host > Add Networking**, after you select a VMkernel network adapter and an existing standard switch, in the **Port properties** page you might not see the VLAD ID. The issue occurs because the VLAN ID component is part of the `network-ui` module, which is lazy loaded and needs a trigger to refresh.

Workaround: Go to **Host > Configure > Networking > Virtual Switches** to trigger the loading of the `network ui` module and the VLAD ID appears.

Vendor providers go offline after a PNID change

When you change the vCenter IP address (PNID change), the registered vendor providers go offline.

Workaround: Re-register the vendor providers.

Cross vCenter migration of a virtual machine fails with an error

When you use cross vCenter vMotion to move a VM's storage and host to a different vCenter server instance, you might receive the error `The operation is not allowed in the current state.`

This error appears in the UI wizard after the Host Selection step and before the Datastore Selection step, in cases where the VM has an assigned storage policy containing host-based rules such as encryption or any other IO filter rule.

Workaround: Assign the VM and its disks to a storage policy without host-based rules. You might need to decrypt the VM if the source VM is encrypted. Then retry the cross vCenter vMotion action.

Storage Sensors information in Hardware Health tab shows incorrect values on vCenter UI, host UI, and MOB

When you navigate to **Host > Monitor > Hardware Health > Storage Sensors** on vCenter UI, the storage information displays either incorrect or unknown values. The same issue is observed on the host UI and the MOB path `"runtime.hardwareStatusInfo.storageStatusInfo"` as well.

Workaround: None.

vSphere UI host advanced settings shows the current product locker location as empty with an empty default

vSphere UI host advanced settings shows the current product locker location as empty with an empty default. This is inconsistent as the actual product location `symlink` is created and valid. This causes confusion to the user. The default cannot be corrected from UI.

Workaround: User can use the esxcli command on the host to correct the current product locker location default as below.

1. Remove the existing Product Locker Location setting with: `"esxcli system settings advanced remove -o ProductLockerLocation"`

2. Re-add the Product Locker Location setting with the appropriate default:

2.a. If the ESXi is a full installation, the default value is `"/locker/packages/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/locker/packages/vmtoolsRepo"`

2.b. If the ESXi is a PXEboot configuration such as autodeploy, the default value is: `"/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/vmtoolsRepo"`

Run the following command to automatically figure out the location: `export PRODUCT_LOCKER_DEFAULT=`readlink /productLocker``

Add the setting: `esxcli system settings advanced add -d "Path to VMware Tools repository" -o ProductLockerLocation -t string -s $PRODUCT_LOCKER_DEFAULT`

You can combine all the above steps in step 2 by issuing the single command:

```
esxcli system settings advanced add -d "Path to VMware Tools repository" -o
ProductLockerLocation -t string -s `readlink /productLocker`
```

Skyline Health page displays garbage characters

In the vSphere Client, when you navigate to vCenter Server or select an ESXi host in the vSphere Client navigator and click Monitor > Skyline Health, the page displays garbage characters in the following locales: Korean, Japanese, German and French.

Workaround: Switch to English locale.

Virtual Machine Management Issues

You cannot add or modify an existing network adapter on a virtual machine

If you try to add or modify an existing network adapter on a virtual machine, the Reconfigure Virtual Machine task might fail with an error such as `Cannot complete operation due to concurrent modification by another operation` in the vSphere Client. In the `/var/log/hostd.log` file of the ESXi host where the virtual machine runs, you see logs such as:

```
2020-07-28T07:47:31.621Z verbose hostd[2102259] [Originator@6876 sub=Vigor.Vmsvc.vm:/vmfs/volumes/vsan:526bc94351cf8f42-41153841cab2f9d9/bad71f5f-d85e-a276-4cf6-246e965d7154/interop_l2vpn_vmotion_VM_1.vmx] NIC: connection control message: Failed to connect virtual device 'ethernet0'.
```

In the `vpxa.log` file, you see entries similar to: `2020-07-28T07:47:31.941Z info vpxa[2101759] [Originator@6876 sub=Default opID=opId-59f15-19829-91-01-ed] [VpxLRO] -- ERROR task-138 -- vm-13 -- vim.VirtualMachine.reconfigure: vim.fault.GenericVmConfigFault:`

Workaround: For each ESXi host in your cluster do the following:

1. Connect to the ESXi host by using SSH and run the command
   `esxcli system module parameters set -a -p dvfiltersMaxFilters=8192 -m dvfilter`
2. Put the ESXi host in Maintenance Mode.
3. Reboot the ESXi host.

For more information, see VMware knowledge base article 80399.

ESXi 6.5 hosts with AMD Opteron Generation 3 (Greyhound) processors cannot join Enhanced vMotion Compatibility (EVC) AMD REV E or AMD REV F clusters on a vCenter Server 7.0 Update 1 system

In vCenter Server 7.0 Update 1, vSphere cluster services, such as vSphere DRS and vSphere HA, run on ESX agent virtual machines to make the services functionally independent of vCenter Server. However, the CPU baseline for AMD processors of the ESX agent virtual machines have POPCNT SSE4A instructions, which prevents ESXi 6.5 hosts with AMD Opteron Generation 3 (Greyhound) processors to enable EVC mode AMD REV E and AMD REV F on a vCenter Server 7.0 Update 1 system.

Workaround: None

The postcustomization section of the customization script runs before the guest customization

When you run the guest customization script for a Linux guest operating system, the `precustomization` section of the customization script that is defined in the customization specification runs before the guest customization and the `postcustomization` section runs after that. If you enable Cloud-Init in the guest operating system of a virtual machine, the `postcustomization` section runs before the customization due to a known issue in Cloud-Init.

Workaround: Deactivate Cloud-Init and use the standard guest customization.

Group migration operations in vSphere vMotion, Storage vMotion, and vMotion without shared storage fail with error

When you perform group migration operations on VMs with multiple disks and multi-level snapshots, the operations might fail with the error `com.vmware.vc.GenericVmConfigFault Failed waiting for data. Error 195887167. Connection closed by remote host, possibly due to timeout.`

Workaround: Retry the migration operation on the failed VMs one at a time.

Deploying an OVF or OVA template from a URL fails with a 403 Forbidden error

The URLs that contain an HTTP query parameter are not supported. For example, `http://webaddress.com?file=abc.ovf` or the Amazon pre-signed S3 URLs.

Workaround: Download the files and deploy them from your local file system.

Importing or deploying local OVF files containing non-ASCII characters in their name might fail with an error

When you import local `.ovf` files containing non-ASCII characters in their name, you might receive `400 Bad Request Error` . When you use such `.ovf` files to deploy a virtual machine in the vSphere Client, the deployment process stops at 0%. As a result, you might receive `400 Bad Request Error` or `500 Internal Server Error` .

Workaround:

1. Remove the non-ASCII characters from the `.ovf` and `.vmdk` file names.
   - To edit the `.ovf` file, open it with a text editor.
   - Search the non-ASCII `.vmdk` file name and change it to ASCII.
2. Import or deploy the saved files again.

New The third level of nested objects in a virtual machine folder is not visible

Perform the following steps:

1. Navigate to a data center and create a virtual machine folder.
2. In the virtual machine folder, create a nested virtual machine folder.
3. In the second folder, create another nested virtual machine, virtual machine folder, vApp, or VM Template.

As a result, from the VMs and Templates inventory tree you cannot see the objects in the third nested folder.

Workaround: To see the objects in the third nested folder, navigate to the second nested folder and select the VMs tab.

vSAN file services operations fail on vSphere Lifecycle Manager-enabled clusters

During a change in the state of an ESXi host, vSAN file services operations might fail on vSphere Lifecycle Manager-enabled clusters due to a race condition with the vSphere ESX Agent Manager (EAM). The problem happens during upgrades and operations, such as power on or power off, booting, or when the host exits maintenance or standby mode. The race condition occurs when an endpoint has been unavailable before the change of state of the ESXi host. In such cases, the EAM starts a remediation process that cannot be resolved and fails operations from other services, such as the vSAN file services.

Workaround: Restart the vSphere ESX Agent Manager.

vSphere HA and Fault Tolerance Issues

VMs in a cluster might be orphaned after recovering from storage inaccessibility such as a cluster wide APD

Some VMs might be in orphaned state after cluster wide APD recovers, even if HA and VMCP are enabled on the cluster.

This issue might be encountered when the following conditions occur simultaneously:

- All hosts in the cluster experience APD and do not recover until VMCP timeout is reached.

- HA primary initiates failover due to APD on a host.
- Power on API during HA failover fails due to one of the following:
  - APD across the same host
  - Cascading APD across the entire cluster
  - Storage issues
  - Resource unavailability
- FDM unregistration and VCs steal VM logic might initiate during a window where FDM has not unregistered the failed VM and VC's host synchronization responds that multiple hosts are reporting the same VM. Both FDM and VC unregister the different registered copies of the same VM from different hosts, causing the VM to be orphaned.

Workaround: You must unregister and reregister the orphaned VMs manually within the cluster after the APD recovers.

If you do not manually reregister the orphaned VMs, HA attempts failover of the orphaned VMs, but it might take between 5 to 10 hours depending on when APD recovers.

The overall functionality of the cluster is not affected in these cases and HA will continue to protect the VMs. This is an anomaly in what gets displayed on VC for the duration of the problem.

vSphere Lifecycle Manager Issues

vSphere Lifecycle Manager and vSAN File Services cannot be simultaneously enabled on a vSAN cluster in vSphere 7.0 release

If vSphere Lifecycle Manager is enabled on a cluster, vSAN File Services cannot be enabled on the same cluster and vice versa. In order to enable vSphere Lifecycle Manager on a cluster, which has VSAN File Services enabled already, first deactivate vSAN File Services and retry the operation. Please note that if you transition to a cluster that is managed by a single image, vSphere Lifecycle Manager cannot be deactivated on that cluster.

Workaround: None.

You cannot edit the VMware vSphere Lifecycle Manager Update Download scheduled task

In the vSphere Client, when you navigate to a vCenter Server instance and select **Scheduled Tasks** under the **Configure** tab, if you select the **VMware vSphere Lifecycle Manager Update Download** task and click **Edit**, you cannot modify the existing settings.

Workaround: You can edit the **VMware vSphere Lifecycle Manager Update Download** task by following the steps in the topic Configure the vSphere Lifecycle Manager Automatic Download Task.

When a hardware support manager is unavailable, vSphere High Availability (HA) functionality is impacted

If hardware support manager is unavailable for a cluster that you manage with a single image, where a firmware and drivers addon is selected and vSphere HA is enabled, the vSphere HA functionality is impacted. You may experience the following errors.

- Configuring vSphere HA on a cluster fails.
- Cannot complete the configuration of the vSphere HA agent on a host: `Applying HA VIBs on the cluster encountered a failure.`
- Remediating vSphere HA fails: `A general system error occurred: Failed to get Effective Component map.`
- Disabling vSphere HA fails: Delete Solution task failed. `A general system error occurred: Cannot find hardware support package from depot or hardware support manager.`

Workaround:

- If the hardware support manager is temporarily unavailable, perform the following steps.

1. Reconnect the hardware support manager to vCenter Server.
2. Select a cluster from the Hosts and Cluster menu.
3. Select the Configure tab.
4. Under Services, click vSphere Availability.
5. Re-enable vSphere HA.

- If the hardware support manager is permanently unavailable, perform the following steps.

1. Remove the hardware support manager and the hardware support package from the image specification
2. Re-enable vSphere HA.
3. Select a cluster from the Hosts and Cluster menu.
4. Select the Updates tab.
5. Click Edit .
6. Remove the firmware and drivers addon and click Save.
7. Select the Configure tab.
8. Under Services, click vSphere Availability.
9. Re-enable vSphere HA.

I/OFilter is not removed from a cluster after a remediation process in vSphere Lifecycle Manager

Removing I/OFilter from a cluster by remediating the cluster in vSphere Lifecycle Manager, fails with the following error message: `iofilter XXX already exists` . The iofilter remains listed as installed.

Workaround:

1. Call IOFilter API `UninstallIoFilter_Task` from the vCenter Server managed object (IoFilterManager).
2. Remediate the cluster in vSphere Lifecycle Manager.
3. Call IOFilter API `ResolveInstallationErrorsOnCluster_Task` from the vCenter Server managed object (IoFilterManager) to update the database.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, disabling and re-enabling vSphere HA causes a vSphere HA error state

Disabling and re-enabling vSphere HA during remediation process of a cluster, may fail the remediation process due to vSphere HA health checks reporting that hosts don't have vSphere HA VIBs installed. You may see the following error message: `Setting desired image spec for cluster failed` .

Workaround: After the cluster remediation operation has finished, deactivate and re-enable vSphere HA for the cluster.

Checking for recommended images in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the recommendation generation task could take more than an hour to finish or may appear to hang. The completion time for the recommendation task depends on the number of devices configured on each host and the number of image candidates from the depot that vSphere Lifecycle Manager needs to process before obtaining a valid image to recommend.

Workaround: None.

Checking for hardware compatibility in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the validation report generation task could take up to 30 minutes to finish or may appear to hang. The completion time depends on the number of devices configured on each host and the number of hosts configured in the cluster.

Workaround: None

Incomplete error messages in non-English languages are displayed, when remediating a cluster in vSphere Lifecycle Manager

You can encounter incomplete error messages for localized languages in the vCenter Server user interface. The messages are displayed, after a cluster remediation process in vSphere Lifecycle Manager fails. For example, your can observe the following error message.

The error message in English language: `Virtual machine 'VMC on DELL EMC -FileServer' that runs on cluster 'Cluster-1' reported an issue which prevents entering maintenance mode: Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

The error message in French language: `La VM « VMC on DELL EMC -FileServer », située sur le cluster « {Cluster-1} », a signalé un problème empêchant le passage en mode de maintenance : Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

Workaround: None.

When you convert a cluster that uses baselines to a cluster that uses a single image, a warning is displayed that vSphere HA VIBs will be removed

Converting a vSphere HA enabled cluster that uses baselines to a cluster that uses a single image, may result a warning message displaying that `vmware-fdm` component will be removed.

Workaround: This message can be ignored. The conversion process installs the `vmware-fdm` component.

If vSphere Update Manager is configured to download patch updates from the Internet through a proxy server, after upgrade to vSphere 7.0 that converts Update Manager to vSphere Lifecycle Manager, downloading patches from VMware patch repository might fail

In earlier releases of vCenter Server you could configure independent proxy settings for vCenter Server and vSphere Update Manager. After an upgrade to vSphere 7.0, vSphere Update Manager service becomes part of the vSphere Lifecycle Manager service. For the vSphere Lifecycle Manager service, the proxy settings are configured from the vCenter Server appliance settings. If you had configured Update Manager to download patch updates from the Internet through a proxy server but the vCenter Server appliance had no proxy setting configuration, after a vCenter Server upgrade to version 7.0, the vSphere Lifecycle Manager fails to connect to the VMware depot and is unable to download patches or updates.

Workaround: Log in to the vCenter Server Appliance Management Interface, https://*vcenter-server-appliance-FQDN-or-IP-address*:5480, to configure proxy settings for the vCenter Server appliance and enable vSphere Lifecycle Manager to use proxy.

If you use a Java client to review remediation tasks, you cannot extract the results from the remediation operations

If you use a Java client to review remediation tasks, extracting the results might fail with a `ConstraintValidationException` error. The issue occurs when an ESXi host fails to enter maintenance mode during the remediation and gets a status SKIPPED, but at the same time wrongly gets an In Progress flag for the consecutive remediation operations. This causes the `ConstraintValidationException` error on the Java Clients and you cannot extract the result of the remediation operation.

Workaround: Fix the underlying issues that prevent ESXi hosts to enter Maintenance Mode and retry the remediation operation.

The general vSphere Lifecycle Manager depot and local depots in Remote Office and Branch Office (ROBO) deployments might not be in sync

ROBO clusters that have limited or no access to the Internet or limited connectivity to vCenter Server can download an image from a depot that is local for them instead of accessing the vSphere Lifecycle Manager depot in vCenter Server. However, vSphere Lifecycle Manager generates software recommendations in the form of pre-validated images only on a central level and a recommended image content might not be available at a depot override.

Workaround: If you decide to use a recommended image, make sure the content between depot overrides and the central depot are in sync.

Cluster remediation by using the vSphere Lifecycle Manager might fail on ESXi hosts with enabled lockdown mode

If a cluster has ESXi hosts with enabled lockdown mode, remediation operations by using the vSphere Lifecycle Manager might skip such hosts. In the log files, you see messages such as `Host scan task failed` and `com.vmware.vcIntegrity.lifecycle.EsxImage.UnknownError An unknown error occurred while performing the operation..`

Workaround: Add the root user to the exception list for lockdown mode and retry the cluster remediation.

You cannot use an ESXi image with OEM content to create clusters by using vSphere Lifecycle Manager workflows after an update

When you update an ESXi image with OEM content, for example Dell ESXi 7.0 Update 2a to Dell ESXi 7.0 Update 3d, some reserved VIBs, such that are present in the VMware base image but overridden by async VIBs packaged by the OEM, might be deleted. The same issue might occur after updating your system by using a non-critical baseline and then update to a higher version by using an ESXi image with OEM content. For example, if you update to 7.0 Update 2 by using a non-critical baseline and then update to 7.0 Update 3 by using a Dell ESXi 7.0 Update 3 image, reserved VIBs might also be deleted. As a result, you cannot use ESXi hosts with the updated version to create a vSphere Lifecycle Manager cluster managed by a single image. The operation fails and in the backtrace, you see errors such as:

```
2021-11-24T09:42:49Z lifecycle: 2101166: HostSeeding:956 ERROR Extract depot failed:
('VMW_bootbank_bnxtroce_216.0.58.0-23vmw.703.0.0.18644231', 'Failed to add reserved
VIB VMW_bootbank_bnxtroce_216.0.58.0-23vmw.703.0.0.18644231: not found in the reserved
VIB cache storage')2021-11-24T09:42:50Z lifecycle: 2101166: imagemanagerctl:373 ERROR
Extract depot failed.021-11-24T09:42:50Z lifecycle: 2101166: imagemanagerctl:152 ERROR
[ReservedVibExtractError] ('VMW_bootbank_bnxtroce_216.0.58.0-23vmw.703.0.0.18644231',
'Failed to add reserved VIB VMW_bootbank_bnxtroce_216.0.58.0-23vmw.703.0.0.18644231: not
found in the reserved VIB cache storage')
```

Workaround: Use interactive or scripted upgrade instead of vSphere Lifecycle Manager workflows.

After you upgrade to vCenter Server 7.0.0b, in the vSphere Lifecycle Manager home view in the vSphere Client, you do not see the Show only rollup updates toggle button

In vCenter Server 7.0.0b, you can use the **Show only rollup updates** toggle button to filter and select patches that you want to include in a baseline when you use the vSphere Lifecycle Manager.

The button is available in the **Updates** tab on the **Lifecycle Manager** pane, **Menu** > **Lifecycle Manager**, which is the vSphere Lifecycle Manager home view in the vSphere Client. The button is also available in the **Select Patches Manually** page on the **Baselines** tab in the **Create Baseline** wizard, which opens when you select **New** > **Baseline**.

However, the **Show only rollup updates** toggle button might not be visible after you upgrade to vCenter Server 7.0.0b.

Workaround: After an upgrade to vCenter Server 7.0.0b, restart the vSphere Client. For more information, see Start, Stop, and Restart Services.

The Show only rollup updates toggle button is always turned on when you open a tab in the vSphere Lifecycle Manager home view in the vSphere Client

In vCenter Server 7.0.0b, you can use the **Show only rollup updates** toggle button to filter and select patches that you want to include in a baseline when you use the vSphere Lifecycle Manager.

The button is available in the **Updates** tab on the **Lifecycle Manager** pane, **Menu** > **Lifecycle Manager**, which is the vSphere Lifecycle Manager home view in the vSphere Client. The button is also available in the **Select Patches Manually** page on the **Baselines** tab in the **Create Baseline** wizard, which opens when you select **New** > **Baseline**.

However, the toggle button appears always turned on when you navigate to either of the **Updates** tab or the **Select Patches Manually** page. Even if you turn off the button when navigating away from the tab or page, it appears still turned on the next time you open them.

Workaround: None

When you use the Update Planner, in the vSphere Client you might see Unexpected error occurred while fetching the updates

When you use Update Planner, which is part of vSphere Lifecycle Manager, used to facilitate vCenter Server updates, you might see the following error in the vSphere Client:

```
Unexpected error occurred while fetching the updates
```

The issue occurs when you use a custom HTTPS port that prevents you from running interoperability reports by using the vSphere Client.

Workaround: Manually invoke the API. For more details, see the vSphere Automation API.

Miscellaneous Issues

When applying a host profile with version 6.5 to a ESXi host with version 7.0, the compliance check fails

Applying a host profile with version 6.5 to a ESXi host with version 7.0, results in Coredump file profile reported as not compliant with the host.

Workaround: There are two possible workarounds.

1. When you create a host profile with version 6.5, set an advanced configuration option VMkernel.Boot.autoCreateDumpFile to false on the ESXi host.
2. When you apply an existing host profile with version 6.5, add an advanced configuration option VMkernel.Boot.autoCreateDumpFile in the host profile, configure the option to a fixed policy, and set value to false.

Cannot migrate container volume due to insufficient space

The Migrate volume dialog in vSphere Client considers the current size of container volumes and the free space available on the target datastores. If the free space of a datastore is less than the volume size, then you cannot select the datastore for migration. vSphere preserves the storage policy as it migrates the volume, but the file size of the volume might change depending on the destination datastore type and its supported features. The vSphere Client might show the datastore has insufficient space to perform the migration, even though enough space is available.

Workaround: None

The Actions drop-down menu does not contain any items when your browser is set to language different from English

When your browser is set to language different from English and you click the **Switch to New View** button from the virtual machine **Summary** tab of the vSphere Client inventory, the **Actions** drop-down menu in the **Guest OS** panel does not contain any items.

Workaround: Select the **Actions** drop-down menu on the top of the virtual machine page.

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit minor throughput degradation when Dynamic Receive Side Scaling (DYN_RSS) or Generic RSS (GEN_RSS) feature is turned on

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit less than 5 percent throughput degradation when DYN_RSS and GEN_RSS feature is turned on, which is unlikely to impact normal workloads.

Workaround: You can deactivate DYN_RSS and GEN_RSS feature with the following commands:

```
# esxcli system module parameters set -m nmlx5_core -p "DYN_RSS=0 GEN_RSS=0"
# reboot
```

RDMA traffic between two VMs on the same host might fail in PVRDMA environment

In a vSphere 7.0 implementation of a PVRDMA environment, VMs pass traffic through the HCA for local communication if an HCA is present. However, loopback of RDMA traffic does not work on qedrntv driver. For instance, RDMA Queue Pairs running on VMs that are configured under same uplink port cannot communicate with each other.

In vSphere 6.7 and earlier, HCA was used for local RDMA traffic if SRQ was enabled. vSphere 7.0 uses HCA loopback with VMs using versions of PVRDMA that have SRQ enabled with a minimum of HW v14 using RoCE v2.

The current version of Marvell FastLinQ adapter firmware does not support loopback traffic between QPs of the same PF or port.

Workaround: Required support is being added in the out-of-box driver certified for vSphere 7.0. If you are using the inbox qedrntv driver, you must use a 3-host configuration and migrate VMs to the third host.

Unreliable Datagram traffic QP limitations in qedrntv driver

There are limitations with the Marvell FastLinQ qedrntv RoCE driver and Unreliable Datagram (UD) traffic. UD applications involving bulk traffic might fail with qedrntv driver. Additionally, UD QPs can only work with DMA Memory Regions (MR). Physical MRs or FRMR are not supported. Applications attempting to use physical MR or FRMR along with UD QP fail to pass traffic when used with qedrntv driver. Known examples of such test applications are `ibv_ud_pingpong` and `ib_send_bw`.

Standard RoCE and RoCEv2 use cases in a VMware ESXi environment such as iSER, NVMe-oF (RoCE) and PVRDMA are not impacted by this issue. Use cases for UD traffic are limited and this issue impacts a small set of applications requiring bulk UD traffic.

Marvell FastLinQ hardware does not support RDMA UD traffic offload. In order to meet the VMware PVRDMA requirement to support GSI QP, a restricted software only implementation of UD QP support was added to the qedrntv driver. The goal of the implementation is to provide support for control path GSI communication and is not a complete implementation of UD QP supporting bulk traffic and advanced features.

Since UD support is implemented in software, the implementation might not keep up with heavy traffic and packets might be dropped. This can result in failures with bulk UD traffic.

Workaround: Bulk UD QP traffic is not supported with qedrntv driver and there is no workaround at this time. VMware ESXi RDMA (RoCE) use cases like iSER, NVMe, RDMA and PVRDMA are unaffected by this issue.

Servers equipped with QLogic 578xx NIC might fail when frequently connecting or disconnecting iSCSI LUNs

If you trigger QLogic 578xx NIC iSCSI connection or disconnection frequently in a short time, the server might fail due to an issue with the qfle3 driver. This is caused by a known defect in the device's firmware.

Workaround: None.

ESXi might fail during driver unload or controller disconnect operation in Broadcom NVMe over FC environment

In Broadcom NVMe over FC environment, ESXi might fail during driver unload or controller disconnect operation and display an error message such as: `@BlueScreen: #PF Exception 14 in world 2098707:vmknvmeGener IP 0x4200225021cc addr 0x19`

Workaround: None.

ESXi does not display OEM firmware version number of i350/X550 NICs on some Dell servers

The inbox ixgben driver only recognizes firmware data version or signature for i350/X550 NICs. On some Dell servers the OEM firmware version number is programmed into the OEM package version region, and the inbox ixgben driver does not read this information. Only the 8-digit firmware signature is displayed.

Workaround: To display the OEM firmware version number, install async ixgben driver version 1.7.15 or later.

X710 or XL710 NICs might fail in ESXi

When you initiate certain destructive operations to X710 or XL710 NICs, such as resetting the NIC or manipulating VMKernel's internal device tree, the NIC hardware might read data from non-packet memory.

Workaround: Do not reset the NIC or manipulate vmkernel internal device state.

NVMe-oF does not guarantee persistent VMHBA name after system reboot

NVMe-oF is a new feature in vSphere 7.0. If your server has a USB storage installation that uses vmhba30+ and also has NVMe over RDMA configuration, the VMHBA name might change after a system reboot. This is because the VMHBA name assignment for NVMe over RDMA is different from PCIe devices. ESXi does not guarantee persistence.

Workaround: None.

Backup fails for vCenter database size of 300 GB or greater

If the vCenter database size is 300 GB or greater, the file-based backup will fail with a timeout. The following error message is displayed: `Timeout! Failed to complete in 72000 seconds`

Workaround: None.

A restore of vCenter Server 7.0 which is upgraded from vCenter Server 6.x with External Platform Services Controller to vCenter Server 7.0 might fail

When you restore a vCenter Server 7.0 which is upgraded from 6.x with External Platform Services Controller to vCenter Server 7.0, the restore might fail and display the following error: `Failed to retrieve appliance storage list`

Workaround: During the first stage of the restore process, increase the storage level of the vCenter Server 7.0. For example if the vCenter Server 6.7 External Platform Services Controller setup storage type is small, select storage type large for the restore process.

Enabled SSL protocols configuration parameter is not configured during a host profile remediation process

`Enabled SSL protocols` configuration parameter is not configured during a host profile remediation and only the system default protocol `tlsv1.2` is enabled. This behavior is observed for a host profile with version 7.0 and earlier in a vCenter Server 7.0 environment.

Workaround: To enable TLSV 1.0 or TLSV 1.1 SSL protocols for SFCB, log in to an ESXi host by using SSH, and run the following ESXCLI command: `esxcli system wbem -P <protocol_name>`

Unable to configure Lockdown Mode settings by using Host Profiles

Lockdown Mode cannot be configured by using a security host profile and cannot be applied to multiple ESXi hosts at once. You must manually configure each host.

Workaround: In vCenter Server 7.0, you can configure Lockdown Mode and manage Lockdown Mode exception user list by using a security host profile.

When a host profile is applied to a cluster, Enhanced vMotion Compatibility (EVC) settings are missing from the ESXi hosts

Some settings in the VMware config file `/etc/vmware/config` are not managed by Host Profiles and are blocked, when the config file is modified. As a result, when the host profile is applied to a cluster, the EVC settings are lost, which causes loss of EVC functionalities. For example, unmasked CPUs can be exposed to workloads.

Workaround: Reconfigure the relevant EVC baseline on cluster to recover the EVC settings.

Using a host profile that defines a core dump partition in vCenter Server 7.0 results in an error

In vCenter Server 7.0, configuring and managing a core dump partition in a host profile is not available. Attempting to apply a host profile that defines a core dump partition, results in the following error: `No valid coredump partition found.`

Workaround: None. In vCenter Server 7.0., Host Profiles supports only file-based core dumps.

You cannot paste by right clicking in the vi editor

If you use the vi text editor on a vCenter Server Appliance instance, you cannot paste previously copied content by right clicking. Instead, the vi editor changes mode to Visual.

Workaround: From the vCenter Server Appliance shell, run the command`/usr/bin/sed -i.bak -E '2alet skip_defaults_vim=1' /etc/vimrc.`

HTTP requests from certain libraries to vSphere might be rejected

The HTTP reverse proxy in vSphere 7.0 enforces stricter standard compliance than in previous releases. This might expose pre-existing problems in some third-party libraries used by applications for SOAP calls to vSphere.

If you develop vSphere applications that use such libraries or include applications that rely on such libraries in your vSphere stack, you might experience connection issues when these libraries send HTTP requests to VMOMI. For example, HTTP requests issued from vijava libraries can take the following form:

```
POST /sdk HTTP/1.1
SOAPAction
Content-Type: text/xml; charset=utf-8
User-Agent: Java/1.8.0_221
```

The syntax in this example violates an HTTP protocol header field requirement that mandates a colon after SOAPAction. Hence, the request is rejected in flight.

Workaround: Developers leveraging noncompliant libraries in their applications can consider using a library that follows HTTP standards instead. For example, developers who use the vijava library can consider using the latest version of the yavijava library instead.

SNMP dynamic firewall ruleset is modified by Host Profiles during a remediation process

The SNMP firewall ruleset is a dynamic state, which is handled during runtime. When a host profile is applied, the configuration of the ruleset is managed simultaneously by Host Profiles and SNMP, which can modify the firewall settings unexpectedly.

Workaround: There are two possible workarounds.

- To allow the ruleset to manage itself dynamically, exclude the SNMP firewall ruleset option in the configuration of the host profile.

- To proceed with the double management of the ruleset, when needed, correct the firewall ruleset state.

You might see a dump file when using Broadcom driver lsi_msgpt3, lsi_msgpt35 and lsi_mr3

When using the lsi_msgpt3, lsi_msgpt35 and lsi_mr3 controllers, there is a potential risk to see dump file lsuv2-lsi-drivers-plugin-util-zdump. There is an issue when exiting the storelib used in this plugin utility. There is no impact on ESXi operations, you can ignore the dump file.

Workaround: You can safely ignore this message. You can remove the lsuv2-lsi-drivers-plugin with the following command:

```
esxcli software vib remove -n lsuv2-lsiv2-drivers-plugin
```

You might see reboot is not required after configuring SR-IOV of a PCI device in vCenter, but device configurations made by third party extensions might be lost and require reboot to be re-applied.

In ESXi 7.0, SR-IOV configuration is applied without a reboot and the device driver is reloaded. ESXi hosts might have third party extensions perform device configurations that need to run after the device driver is loaded during boot. A reboot is required for those third party extensions to re-apply the device configuration.

Workaround: You must reboot after configuring SR-IOV to apply third party device configurations.

You see black or grey zones in the background of a parent window in the Direct Console User Interface (DCUI) after a child window closes

In the DCUI, when you close a child window by pressing the ESC or Enter keys, or the **Cancel** or **OK** buttons, the parent window appearance might change. The background color changes to grey or black for some part of the parent window. However, all required information from the DCUI is properly displayed and all operations performed in the DCUI complete successfully.

Workaround: Wait for 1 minute without refreshing the current window in the DCUI or pressing any key.

Backup Issues

If you use the NFS and SMB protocols for file-based backup of vCenter Server, the backup fails after an update from vCenter Server 7.x to vCenter Server 7.0 Update 1

If you use the Network File System (NFS) and Server Message Block (SMB) protocols for file-based backup of vCenter Server, the backup fails after an update from an earlier version of vCenter Server 7.x to vCenter Server 7.0 Update 1. In the `applmgmt.log` , you see an error message such as `Failed to mount the remote storage` . The issue occurs because of Linux kernel updates that run during the patch process. The issue does not occur on fresh installations of vCenter Server 7.0 Update 1.

Workaround: Reboot the vCenter Server appliance after the update is complete.

Microsoft Active Directory Federation Services (ADFS) logins might fail after restoring a vCenter Server Appliance

If you manually add a certificate to the vCenter Server JRE truststore or modify the `/etc/hosts` file when setting up ADFS, the changes are not preserved after restoring and might cause ADFS logins to fail.

Workaround: Add the ADFS certificate to the vCenter Server JRE truststore after restoring your vCenter Server Appliance. For more information, see Import the Trusted Certificate of an External Identity Provider. Add the necessary host name mappings back to the `/etc/hosts` file after restoring your vCenter Server Appliance.

vSAN Issues

Higher than actual vSAN storage pool free space estimate might lead to unexpected storage shortages

The `freeSpace` parameter of a vSAN storage pool might not exclude disks with errors and display the unused space estimate as higher than the actual. As a result, you might see unexpected storage shortages. This issue only affects vSAN storage pools.

Workaround: Manually compute the storage capacity by disregarding the `freeSpace` value of disks with errors from the overall storage capacity provided by the `freeSpace` parameter of the storage pool.

Server Configuration Issues

You see a message Error retrieving when trying to view the status of Key Management Server (KMS) instances in the vSphere Client

In the vSphere Client, you might see a message `Error retrieving` for several minutes when trying to view Key Management Server (KMS) instances. The issue occurs when a KMS instance in a standard key provider loses connectivity. Until all network requests to the affected KMS time out, which takes around 4 minutes, you cannot see the status of any KMS instance in your system, only the error message for the key provider. After the timeout, you can see the status of all KMS instances.

Workaround: If you see the Error retrieving message, wait for 4 minutes.

Due to a default timeout setting of 2 minutes, log in to vCenter instances in Enhanced Linked Mode takes long when any of the vCenters is down

When you have a number of vCenter instances in Enhanced Linked Mode, if one of the instances is down for some reason, such as maintenance, log in to the other instances might take up to 2 minutes, which is the default timeout setting. Changing the timeout property that specifies the wait time for log in to linked vCenter instances is a complex task that requires manually editing the `LinkedVcGroup.login.timeout` property located in `vim-commons-vsphere.properties` . To simlify the task, starting with vCenter Server 7.0 Update 3l, the setting `LinkedVcGroup.login.timeout=120000` moves from `vim-commons-vsphere.properties` to the `webclient.properties` file. Editing this option allows you to reduce the wait time so that if one of the vCenter logins is taking more time, it does not affect the log in time for other instances.

Workaround: Edit `/etc/vmware/vsphere-ui/webclient.properties` and change the value of `LinkedVcGroup.login.timeout` from `120000` to a smaller value in milliseconds, but consider that a value of `<= 0` is an infinite timeout.

VMware vCenter Server 7.0 Update 3v Release Notes

This document contains the following sections

- Introduction
- What's New
- Upgrade Notes
- Patches Contained in This Release
- Resolved Issues
- Known Issues
- Known Issues from Prior Releases

Introduction

VMware vCenter Server 7.0 Update 3v | 20 MAY 2025 | ISO Build 24730281 Check for additions and updates to these release notes.

What's New

- For vCenter Server 7.0 Update 3v updates, see the **Resolved Issues** and **Known Issues** sections.
- For vSphere Supervisor updates, see the vSphere Supervisor Release Notes.
- For Photon OS updates, see VMware vCenter Server Appliance Photon OS Security Patches.

This release resolves CVE-2025-41225. For more information on this vulnerability and its impact on Broadcom products, see VMSA-2025-0010.

Prefix-Based MAC Address Allocation by the vCenter GUI Installer and CLI:

vCenter 7.0 Update 3v adds the option to use prefix-based allocation to specify an OUI other than the default one 00:50:56 by Broadcom, or to introduce Locally Administered MAC Addresses (LAA) for a larger address space, by using either the vCenter GUI installer or the CLI installer. After deploying a vCenter instance, you can use the vSphere Client to switch between the available allocation schemes.

Upgrade Notes

Upgrading from vCenter 7.0 Update 3v to vCenter 8.0 Update 3e is not supported due to back-in-time release restrictions. For more information, see KB 67077.

Patches Contained in This Release

Patch for VMware vCenter Server Appliance 7.0 Update 3v

Download Filename	VMware-vCenter-Server-Appliance-7.0.3.02400-24730281-patch-FP.iso
Build	24730281

md5sum	33bb110f457ec1d06054cb4362476c22
sha256checksum	00d688b44ff746e59ba9c5cf60d4c6dc791ba70814f46102795f506717973ef4
PRs fixed	3404100, 3404108, 3471234, 3503319, 3484455, 3484244, 3245536, 3426087, 3473337, 3407726, 3384385, 3418166, 3367090, 3444766, 3468763, 3486798, 3419045
CVEs	CVE-2025-41225

Download and Installation

Log in to the Broadcom Support Portal to download this patch.

For download instructions for earlier releases, see Download Broadcom products and software.

For more information on using the vCenter Server shells, see VMware knowledge base article 2100508.

For more information on patching vCenter Server, see Patching the vCenter Server Appliance.

For more information on staging patches, see Stage Patches to vCenter Server Appliance.

For more information on installing patches, see Install vCenter Server Appliance Patches.

For more information on patching using the Appliance Management Interface, see Patching the vCenter Server by Using the Appliance Management Interface.

Resolved Issues

vCenter and vSphere Client Issues

PR 3404100: vCenter performance stats shows incorrect aggregate values when the data is rolled up to the daily partition

Without date rounding logic, the partition index might start at a random hour instead of 00:00:00, leading to incorrect aggregate values when the data is rolled up to the daily partition.

This issue is resolved in this release.

PR 3404108: Rollup processing of performance stats data in vCenter occurs only by the average rollup type

In vCenter performance statistics, you see only the average value of each duration, regardless if the rollup type is different, such as summation or latest.

This issue is resolved in this release.

PR 3471234: Smart card authentication on vCenter intermittently fails with the error "Unable to validate submitted credentials"

The Certificate Revocation List (CRL) cache updates hourly and if you log in to vCenter by using a smart card during such an hourly cycle in which the old CRL is expired but no new CRL is downloaded, the login fails. Since this is a corner case, smart card authentication on vCenter intermittently fails and in the vSphere Client, you see the error `Unable to validate submitted credentials.`

This issue is resolved in this issue.

PR 3503319: The vpxd service fails because the Guest OS customization API requires IPv4 settings

When you use API to create a Guest Customization Specification and customize the guest OS of a virtual machine, you might need to enter IPv4 settings in the specification or the vpxd service fails with a core dump.

This issue is resolved in this release.

PR 3484455: Distributed Resource Scheduler (DRS) fails to migrate an encrypted VM with an error for missing [Cryptographic operations > Migrate] privileges

In some cases, when DRS schedules to migrate an encrypted VM, it might use the context of a user without `Cryptographer.Migrate` privilege and migration fails with an error in the vSphere Client such as: `Permission to perform this operation was denied. You do not hold privileges "virtual machine vm-xx : [Cryptographic operations > Migrate].`

In the vpxd.log, you see error messages such as:

```
YYYY-MM-DDThh:mm:ss.472Z info vpxd[06061] [Originator@6876 sub=drsExec opID=<op_id>]
Executing DRM recommended vMotion in [vim.ClusterComputeResource:domain-c<id>,esxi_name],
migrating [vim.VirtualMachine:vm-<vm_id>,vm_name] from vim.HostSystem:host-<src_id> to
vim.HostSystem:host-<dstn_id>……..
```

```
YYYY-MM-DDThh:mm:ss.494Z info vpxd[06061] [Originator@6876 sub=pbm opID=<op_id>-01] pre
migrate callback is skipped - for cached from pre migrate check reason
```

```
YYYY-MM-DDThh:mm:ss.494Z warning vpxd[06061] [Originator@6876 sub=CryptoManager
opID=<op_id>-01] The session xx-yy-zz of user DOMAIN\user_name does not have privilege
Cryptographer.Migrate on entity [vim.VirtualMachine:vm-<vm_id>,vm_name].
```

This issue is resolved in this release.

PR 3484244: A rare race condition might cause repeating failovers due to a failure of the vCenter vpxd service or the vSphere Client becoming unresponsive

A rare race condition during a VAPI call from the vpxd service to a virtual machine that coincides with the deletion of a `VirtualMachine` object might cause the vpxd service to fail. As a result, you see repeating failovers or the vSphere Client might become unresponsive.

This issue is resolved in this release.

PR 3245536: When an ESXi host has multiple management IP addresses, in some vSphere Client workflows you might see a "Host not reachable" error

You can assign multiple management IP addresses to a single ESXi host and it is not necessary that all IP addresses are reachable from vCenter at any time. However, if vCenter picks a currently unreachable IP during a workflow that you run from the vSphere Client, such as a remediation precheck, the task might fail with a `Host not reachable` error.

This issue is resolved in this release.

Networking Issues

PR 3351967: Stale NSX properties from ESXi hosts that vCenter might use can cause various networking issues

In some cases, vCenter might retrieve NSX properties from ESXi hosts, save them on the vCenter database and push these NSX properties back to ESXi hosts in various scenarios that can cause the following issues:

1. A virtual switch gets out of sync because vCenter pushes stale NSX properties to an ESXi host.
2. You cannot remove the NSX VIB after you remove a transport node, because vCenter pushes NSX properties back to the virtual switch.
3. After an ESXi host reboot, vCenter feeds stale NSX properties back to the virtual switch.
4. NSX cannot start on a virtual switch due to stale NSX properties.

Logs are different in each case, but you can confirm the issue by checking the `VPX_DVS_BLOB` table in the vCenter DB. If you see NSX properties in the `VPX_DVS_BLOB` table, the issue exists. Look for properties such as:

`com.vmware.nsx.kcp.enable`

`com.vmware.nsx.spf.enabled`

`com.vmware.nsx.vdl2.enabled`

`com.vmware.vswitch.disabled`

`com.vmware.host.feature.container`

`com.vmware.nsx.ens.loadbal`

`com.vmware.nsx.ens.overlayl2flow`

This issue is resolved in this release.

PR 3426087: You see duplicate routes in the Netplan configuration file after guest OS customization on Ubuntu VMs

For Ubuntu releases that support the Netplan utility for configuring networking on a Linux system, when you deploy an Ubuntu VM and customize it with both IPv4 and IPv6 gateways, the Netplan configuration file `/etc/netplan/99-netcfg-vmware.yaml` of the guest OS contains two route sections under a single network interface.

This issue is resolved in this release. With the fix, customizing an Ubuntu VM with both IPv4 and IPv6 gateways creates a single route section for each NIC in the Netplan configuration file, and adds the corresponding IPv4 and IPv6 gateways of the NIC to its route section.

PR 3473337: In the vSphere Client, you still see an NSX overlay segment after deleting it from the NSX Manager

When adding NSX port groups on a vCenter system, vCenter uses an API call to push the port groups to ESXi hosts, but in some cases the call does not complete on all hosts, if a host is temporarily disconnected for example. As a result, from

vCenter perspective, all port groups exist, but from ESXi hosts perspective, some might not exist. Consequently, when you try to delete an NSX overlay segment from the NSX Manager, it still shows in the vSphere Client, because not all port groups can be removed.

This issue is resolved in this release.

PR 3407726: If the Key Management Server (KMS) sends a response not in Key Management Interoperability Protocol (KMIP) format, the vpxd service might fail

In rare cases, KMS might send a response that does not follow the KMIP protocol, which leads to the use of an invalid address in analyzing the response and in turn causes the vpxd service to fail.

This issue is resolved in this release.

PR 3384385: The vpxd service fails after the Mobility Agent (MA) host for VMware HCX is reconnected or redeployed

When you reconnect or redeploy the MA service, which is the data proxy for vSphere vMotion in HCX between onprem and cloud migrations, as a host object in vCenter, the vpxd service might fail due to duplicate entries in the vCenter database. In the vpxd log, you see messages such as `ODBC error: (23505) - ERROR: duplicate key value violates unique constraint "pk_vpx_nw_assignment.`

This issue is resolved in this release.

PR 3418166: You don't see newly created NSX Distributed Virtual port groups on some ESXi hosts

When multiple ESXi hosts join a new transport zone, a race condition in the vCenter host sync handler might cause some ESXi hosts to fail saving the new transport zones configuration. As a result, you don't see newly created NSX Distributed Virtual port groups in the new transport zone on such hosts.

This issue is resolved in this release.

Miscellaneous Issues

PR 3367090: Changes in the authorization roles on an ESXi host are not persistent across reboots

Due to an issue with saving changes to the underlying storage, modifications of the authorization roles on an ESXi host, such as adding a privilege, might not persist across reboots.

This issue is resolved in this release.

PR 3444766: vCenter CPU utilization reaches 100% and the vCenter system becomes slow or unresponsive

After several days of uptime, due to an issue with the Apache HttpCore library, the vCenter CPU utilization by the `vsphere-ui` service might reach 100% and the vCenter system becomes slow or unresponsive.

This issue is resolved in this release.

Upgrade Issues

PR 3468763: During upgrade, the prefix-based MAC allocation scheme configuration is not migrated to the target vCenter

Due to an issue with the configuration path, the prefix-based MAC allocation scheme configuration might not be migrated to the target vCenter during an upgrade.

This issue is resolved in this release.

PR 3486798: ESXi host update or upgrade fails with errors for running out of memory

When an ESXi host enters maintenance mode, it might not clear the resource pool mirror and reservations for the mirror before the evacuations of the last VM are not freed. This leads to insufficient memory being available for upgrade or

update, especially if the last VM that is evacuated has a large reservation, such as tens of GBs. In the backtrace, you see an error such as `Admission failure in path: host:system:kernel:stagebootbank`.

This issue is resolved in this release.

vSAN Issues

PR 3419045: vSAN tasks fail with NotSupported exception

In vSAN HCI with datastore sharing environment (formerly HCI Mesh), a vSAN datastore that belongs to one vSAN cluster can be mounted on hosts of other clusters. Such hosts provide only compute and not storage, and might not even have vSAN active. In the Site Recovery Manager reprotect workflow, if a certain API call is made to a host with no active vSAN, the call ends with a `NotSupported` exception. If such a call is made to a vSAN-enabled compute-only host, then you see no error, but the call does not return any results.

This issue is resolved in this release. The fix makes sure API calls for the SRM reprotect workflow to pick up only hosts with active vSAN.

Known Issues

vCenter and vSphere Client Issues

If the vCenter certificate mode is set to thumbprint or custom, you cannot export logs by using the vSphere Client

If for some reason the advanced setting `vpxd.certmgmt.mode` in a vCenter instance is set to `thumbprint`, which is recommended only as a fallback option, or `custom`, you cannot export logs by using the vSphere Client.

Workaround: Change the `vpxd.certmgmt.mode` setting to `vmca`.

You cannot upload log packages to a VMware service request by using the vSphere Client

You cannot upload log packages to a VMware service request by navigating in the vSphere Client to **Administration > Support > Upload File to Service Request**. Instead, you see a link to a KB article that provides steps to upload log bundles in the Broadcom Support Portal. This is expected.

Workaround: Follow the steps in Uploading files to cases on the Broadcom Support Portal.

Security Issues

Update Manager Download Service (UMDS) stores proxy passwords in plain text

When UMDS accesses a VMware online depot by using a proxy, if you have configured a proxy password, it is stored in the configuration as plain text, which in some environments might be a security concern.

Workaround: Instead of configuring a password, you can pass the password every time you run a `Downland (-D)` and `Re-Download (-R)` command. For example, `./vmware-umds -D --proxy-username "<your_username>" --proxy-password "<your_password>" --proxy-port 80 --proxy-ip 1.1.1.1`.

Known Issues from Prior Releases

vSphere Cluster Services Issues

If all vSphere Cluster Service agent virtual machines in a cluster are down, vSphere DRS does not function in the cluster

If vSphere Cluster Service agent virtual machines fail to deploy or power on in a cluster, services such as vSphere DRS might be impacted.

Workaround: For more information on the issue and workarounds, see VMware knowledge base article 79892.

System virtual machines that support vSphere Cluster Services might impact cluster and datastore maintenance workflows

In vCenter Server 7.0 Update 1, vSphere Cluster Services adds a set of system virtual machines in every vSphere cluster to ensure the healthy operation of vSphere DRS. The system virtual machines deploy automatically with an implicit datastore selection logic. Depending on your cluster configuration, the system virtual machines might impact some of the cluster and datastore maintenance workflows.

Workaround: For more information on the impacted workflows and possible workarounds, see VMware knowledge base articles 79892 and 80483.

Installation, Upgrade, and Migration Issues

Upgrade to vSphere 7.0 Update 3c might require additional steps to force a full host-sync

The supported upgrade sequence for vSphere systems is first to upgrade vCenter Server and then ESXi. However, in certain environments with ESXi hosts of version 7.0 Update 2d and later, you need to update ESXi first to 7.0 Update 3c and then vCenter Server. Such an upgrade sequence requires additional steps to force a full host-sync.

Workaround: Log in to the appliance shell as a user with super administrative privileges (for example, `root`) and follow these steps:

1. Stop the vpxd service.
2. Run the command `/opt/vmware/vpostgres/current/bin/psql -U postgres -d VCDB -c "update VPX_HOST_SYNC_GEN set master_gen=0 where host_id in (select id from VPX_HOST where product_version like '7.0.3%')"`.
3. Start the vpxd service.

Patching vCenter to version 7.0 Update 3q might fail due to unsupported TLS ciphers in the Envoy proxy configuration

During the update of a vCenter instance to version 7.0 Update 3q, some services might fail to start due to custom configuration of the TLS cipher suites in the file `/etc/vmware-rhttpproxy/config.xml` . As a result, in the vSphere Client you see a warning such as `An error occurred while starting service 'vpxd-svcs'` and the process fails. If you use the Virtual Appliance Management Interface, you see an error such as `Installation Failed - Exception occurred in postInstallHook.`

Workaround: See KB 369485 for steps how to reset the TLS ciphers to their defaults and retry the vCenter update.

Hot-patched ESXi hosts with both i40en and i40enu Intel network drivers installed might fail to configure vSphere High Availability after upgrade to vCenter Server 7.0 Update 3c

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3c adds an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. However, if you apply an ESXi hot patch that is released after vCenter Server 7.0 Update 3c and then upgrade your system to vCenter Server 7.0 Update 3c, the hot patch might not be listed in the precheck. As a result, you might not follow the proper steps to the upgrade and vSphere HA might fail to configure on such hosts.

Workaround: Upgrade the hot-patched ESXi hosts to version 7.0 Update 3c.

The vCenter Upgrade/Migration pre-checks fail with "Unexpected error 87"

The vCenter Server Upgrade/Migration pre-checks fail when the Security Token Service (STS) certificate does not contain a Subject Alternative Name (SAN) field. This situation occurs when you have replaced the vCenter 5.5 Single Sign-On

certificate with a custom certificate that has no SAN field, and you attempt to upgrade to vCenter Server 7.0. The upgrade considers the STS certificate invalid and the pre-checks prevent the upgrade process from continuing.

Workaround: Replace the STS certificate with a valid certificate that contains a SAN field then proceed with the vCenter Server 7.0 Upgrade/Migration.

Problems upgrading to vSphere 7.0 with pre-existing CIM providers

After upgrade, previously installed 32-bit CIM providers stop working because ESXi requires 64-bit CIM providers. Customers may lose management API functions related to CIMPDK, NDDK (native DDK), HEXDK, VAIODK (IO filters), and see errors related to **uwglibc** dependency.

The syslog reports module missing, "32 bit shared libraries not loaded."

Workaround: There is no workaround. The fix is to download new 64-bit CIM providers from your vendor.

Patching to vCenter Server 7.0 Update 1 from earlier versions of vCenter Server 7.x is blocked when vCenter Server High Availability is enabled

Patching to vCenter Server 7.0 Update 1 from earlier versions of vCenter Server 7.x is blocked when vCenter Server High Availability is active.

Workaround: To patch your system to vCenter Server 7.0 Update 1 from earlier versions of vCenter Server 7.x, you must remove vCenter Server High Availability and delete the passive and witness nodes. After the upgrade, you must re-create your vCenter Server High Availability clusters.

Migration of a 6.7.x vCenter Server system to vCenter Server 7.x fails with an UnicodeEncodeError

If you select the option to import all data for configuration, inventory, tasks, events, and performance metrics, the migration of a 6.7.x vCenter Server system to vCenter Server 7.x might fail for any vCenter Server system that uses a non-English locale. At step 1 of stage 2 of the migration, in the vSphere Client, you see an error such as:

```
Error while exporting events and tasks data: …ERROR UnicodeEncodeError: Traceback (most recent call last):
```

Workaround: You can complete the migration operation by doing either:

- Select the default option **Configuration and Inventory** at the end of stage 1 of the migration. This option does not include tasks and events data.
- Clean the data in the events tables and run the migration again.

If a Windows vCenter Server system has a database password containing non-ASCII characters, pre-checks of the VMware Migration Assistant fail

If you try to migrate a 6.x vCenter Server system to vCenter Server 7.x by using the VMware Migration Assistant, and your system has a Windows OS, and uses an external database with a password containing non-ASCII characters, the operation fails. For example, Admin!23迁移. In the Migration Assistant console, you see the following error:

```
Error:Component com.vmware.vcdb failed with internal errorResolution:File Bugzilla PR to VPX/VPX/vcdb-upgrade
```

Workaround: None

During an update from vCenter Server 7.x to vCenter Server 7.0 Update 1, you get prompts to provide the vCenter Single Sign-On password

During an update from vCenter Server 7.x to vCenter Server 7.0 Update 1, you get prompts to provide vCenter Single Sign-On administrator password.

Workaround: If you run the update by using the vCenter Server Management Interface, you must provide the vCenter Single Sign-On administrator password.

If you run the update by using software-packages or CLI in an interactive manner, you must interactively provide the vCenter Single Sign-On administrator password.

If you run the update by using software-packages or CLI in a non-interactive manner, you must provide the vCenter Single Sign-On administrator password by an answer file in the format

```
{ "vmdir.password": "SSO Password of Administrator@<SSO-DOMAIN> user" }
```

Smart Card and RSA SecurID authentication might stop working after upgrading to vCenter Server 7.0

If you have configured vCenter Server for either Smart Card or RSA SecurID authentication, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057 before starting the vSphere 7.0 upgrade process. If you do not perform the workaround as described in the KB, you might see the following error messages and Smart Card or RSA SecurID authentication does not work.

"Smart card authentication may stop working. Smart card settings may not be preserved, and smart card authentication may stop working."

or

"RSA SecurID authentication may stop working. RSA SecurID settings may not be preserved, and RSA SecurID authentication may stop working."

Workaround: Before upgrading to vSphere 7.0, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057.

You might not be able to apply or remove NSX while you add ESXi hosts by using a vSphere Lifecycle Manager image to a cluster with enabled VMware vSphere High Availability

If you start an operation to apply or remove NSX while adding multiple ESXi hosts by using a vSphere Lifecycle Manager image to a vSphere HA-enabled cluster, the NSX-related operations might fail with an error in the vSphere Client such as:

```
vSphere HA agent on some of the hosts on cluster <cluster_name> is neither vSphere HA master agent nor connected to vSphere HA master agent. Verify that the HA configuration is correct.
```

The issue occurs because vSphere Lifecycle Manager configures vSphere HA for the ESXi hosts being added to the cluster one at a time. If you run an operation to apply or remove NSX while vSphere HA configure operations are still in progress, NSX operations might queue up between the vSphere HA configure operations for two different ESXi hosts. In such a case, the NSX operation fails with a cluster health check error, because the state of the cluster at that point does not match the expected state that all ESXi hosts have vSphere HA configured and running. The more ESXi hosts you add to a cluster at the same time, the more likely the issue is to occur.

Workaround: Deactivate and enable Sphere HA on the cluster. Proceed with the operations to apply or remove NSX.

After an upgrade of a vCenter Server 7.0 system, you cannot see the IP addresses of pods in the vSphere Pod Summary tab of the vSphere Client

If you upgrade your vCenter Server 7.0 system to a later version, you can no longer see the IP addresses of pods in the **vSphere Pod Summary** tab of the vSphere Client.

Workaround: Use the Kubernetes CLI Tools for vSphere to review details of pods:

1. As a prerequisite, copy the pod and namespace names.
   - In the vSphere Client, navigate to **Workload Management** > **Clusters.**

- Copy the IP displayed in the **Control Plane Node IP Address** tab.
- You can navigate to `https://<control_plane_node_IP_address>` and download the Kubernetes CLI Tools, `kubectl` and `kubectl-vsphere`.
  Alternatively, follow the steps in Download and Install the Kubernetes CLI Tools for vSphere.

2. Use the CLI plug-in for vSphere to review the pod details.
   a. Log in to the Supervisor cluster by using the command
      `kubectl vsphere login --server=https://<server_adress> --vsphere-username <your user account name> --insecure-skip-tls-verify`
   b. By using the names copied in step 1, run the commands for retrieving the pod details:
      `kubectl config use-context <namespace_name>`
      and
      `kubectl describe pod <pod_name> -n <namespace_name>`

As a result, you can see the IP address in an output similar to:

```
$ kubectl describe pod helloworld -n my-podvm-ns ...

Status: Running

IP: 10.0.0.10

IPs:

IP: 10.0.0.10 ...
```

Upgrading a vCenter Server with an external Platform Services Controller from 6.7u3 to 7.0 fails with VMAFD error

When you upgrade a vCenter Server deployment using an external Platform Services Controller, you converge the Platform Services Controller into a vCenter Server appliance. If the upgrade fails with the error `install.vmafd.vmdir_vdcpromo_error_21`, the VMAFD firstboot process has failed. The VMAFD firstboot process copies the VMware Directory Service Database (data.mdb) from the source Platform Services Controller and replication partner vCenter Server appliance.

Workaround: Deactivate TCP Segmentation Offload (TSO) and Generic Segmentation Offload (GSO) on the Ethernet adapter of the source Platform Services Controller or replication partner vCenter Server appliance before upgrading a vCenter Server with an external Platform Services Controller. See Knowledge Base article: https://kb.vmware.com/s/article/74678

vCenter Server system upgrades fail in the pre-check stage

Upgrades of your vCenter Server system might fail in the pre-check stage due to a limit in the authorization (Authz) connections. In the `/var/log/vmware/vpxd-svcs/vpxd-svcs*.log` file you see entries such as:

`Session count for user [after add]: <DOMAIN-NAME>\machine-xxxx is 200Session limit reached for user: <DOMAIN-NAME>\machine-xxxx with 200 sessions.`

You might also see delayed response from the vSphere Client to load the inventory.

Workaround: Restart vmware-vpxd-svcs in your vCenter Server system by using the command `service-control --restart vmware-vpxd-svcs`. Use the command only when no other activity runs in the vCenter Server system to avoid any interruptions to the workflow. For more information, see VMware knowledge base article 81953.

Upgrading vCenter Server using the CLI incorrectly preserves the Transport Security Layer (TLS) configuration for the vSphere Authentication Proxy service

If the vSphere Authentication Proxy service (`vmcam`) is configured to use a particular TLS protocol other than the default TLS 1.2 protocol, this configuration is preserved during the CLI upgrade process. By default, vSphere supports the TLS

1.2 encryption protocol. If you must use the TLS 1.0 and TLS 1.1 protocols to support products or services that do not support TLS 1.2, use the TLS Configurator Utility to enable or deactivate different TLS protocol versions.

Workaround: Use the TLS Configurator Utility to configure the `vmcam` port. To learn how to manage TLS protocol configuration and use the TLS Configurator Utility, see the *VMware Security* documentation.

You do not see a precheck error when patching to vCenter Server 7.0 Update 3c by using CLI

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3c adds an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. In some cases, if such hosts exist in your system, patching from an vCenter Server version earlier than 7.0 Update 3 to a version later than 7.0 Update 3 by using CLI might fail with the error `Installation failed. Retry to resume from the current state. Or please collect the VC support bundle.`.

However, instead of this error, you must see the precheck error message.

Workaround: If you do not see the precheck error and patching your system to vCenter Server 7.0 Update 3c fails, make sure all ESXi hosts are upgraded to ESXi 7.0 Update 3c or higher, by using either a baseline created from an ISO or a single image, before upgrading vCenter Server. Do not use patch baselines based on the rollup bulletin. You can find additional debug log information at `/var/log/vmware/applmgmt` . For more details, see VMware knowledge base articles 87319 and 86447.

Smart card and RSA SecurID settings may not be preserved during vCenter Server upgrade

Authentication using RSA SecurID will not work after upgrading to vCenter Server 7.0. An error message will alert you to this issue when attempting to login using your RSA SecurID login.

Workaround: Reconfigure the smart card or RSA SecureID.

Upgrade to vSphere 7.0 Update 3c might require additional steps to force a full host-sync

The supported upgrade sequence for vSphere systems is first to upgrade vCenter Server and then ESXi. However, in certain environments with ESXi hosts of version 7.0 Update 2c and later, you need to update ESXi first to 7.0 Update 3c and then vCenter Server. Such an upgrade sequence requires additional steps to force a full host-sync.

Workaround: Log in to the appliance shell as a user with super administrative privileges (for example, `root`) and follow these steps:

1. Stop the vpxd service.
2. Run the command `/opt/vmware/vpostgres/current/bin/psql -U postgres -d VCDB -c "update VPX_HOST_SYNC_GEN set master_gen=0 where host_id in (select id from VPX_HOST where product_version like '7.0.3%')"`.
3. Start the vpxd service.

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with network error message

Migration of vCenter Server for Windows to vCenter Server appliance 7.0 fails with the error message `IP already exists in the network`. This prevents the migration process from configuring the network parameters on the new vCenter Server appliance. For more information, examine the log file: `/var/log/vmware/upgrade/UpgradeRunner.log`

Workaround:

1. Verify that all Windows Updates have been completed on the source vCenter Server for Windows instance, or deactivate automatic Windows Updates until after the migration finishes.
2. Retry the migration of vCenter Server for Windows to vCenter Server appliance 7.0.

Hot-patched ESXi hosts with both i40en and i40enu Intel network drivers installed might fail to configure vSphere High Availability after upgrade to vCenter Server 7.0 Update 3c

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3c adds an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. However, if you apply an ESXi hot patch that is released after vCenter Server 7.0 Update 3c and then upgrade your system to vCenter Server 7.0 Update 3c, the hot patch might not be listed in the precheck. As a result, you might not follow the proper steps to the upgrade and vSphere HA might fail to configure on such hosts.

Workaround: Upgrade the hot-patched ESXi hosts to version 7.0 Update 3c.

When you configure the number of virtual functions for an SR-IOV device by using the max_vfs module parameter, the changes might not take effect

In vSphere 7.0, you can configure the number of virtual functions for an SR-IOV device by using the Virtual Infrastructure Management (VIM) API, for example, through the vSphere Client. The task does not require reboot of the ESXi host. After you use the VIM API configuration, if you try to configure the number of SR-IOV virtual functions by using the `max_vfs` module parameter, the changes might not take effect because they are overridden by the VIM API configuration.

Workaround: None. To configure the number of virtual functions for an SR-IOV device, use the same method every time. Use the VIM API or use the `max_vfs` module parameter and reboot the ESXi host.

Upgraded vCenter Server appliance instance does not retain all the secondary networks (NICs) from the source instance

During a major upgrade, if the source instance of the vCenter Server appliance is configured with multiple secondary networks other than the VCHA NIC, the target vCenter Server instance will not retain secondary networks other than the VCHA NIC. If the source instance is configured with multiple NICs that are part of VDS port groups, the NIC configuration will not be preserved during the upgrade. Configurations for vCenter Server appliance instances that are part of the standard port group will be preserved.

Workaround: None. Manually configure the secondary network in the target vCenter Server appliance instance.

After upgrading or migrating a vCenter Server with an external Platform Services Controller, users authenticating using Active Directory lose access to the newly upgraded vCenter Server instance

After upgrading or migrating a vCenter Server with an external Platform Services Controller, if the newly upgraded vCenter Server is not joined to an Active Directory domain, users authenticating using Active Directory will lose access to the vCenter Server instance.

Workaround: Verify that the new vCenter Server instance has been joined to an Active Directory domain. See Knowledge Base article: https://kb.vmware.com/s/article/2118543

Migrating a vCenter Server for Windows with an external Platform Services Controller using an Oracle database fails

If there are non-ASCII strings in the Oracle events and tasks table the migration can fail when exporting events and tasks data. The following error message is provided: UnicodeDecodeError

Workaround: None.

After an ESXi host upgrade, a Host Profile compliance check shows non-compliant status while host remediation tasks fail

The non-compliant status indicates an inconsistency between the profile and the host.

This inconsistency might occur because ESXi 7.0 does not allow duplicate claim rules, but the profile you use contains duplicate rules. For example, if you attempt to use the Host Profile that you extracted from the host before upgrading ESXi

6.5 or ESXi 6.7 to version 7.0 and the Host Profile contains any duplicate claim rules of system default rules, you might experience the problems.

Workaround:

1. Remove any duplicate claim rules of the system default rules from the Host Profile document.
2. Check the compliance status.
3. Remediate the host.
4. If the previous steps do not help, reboot the host.

Error message displays in the vCenter Server Management Interface

After installing or upgrading to vCenter Server 7.0, when you navigate to the Update panel within the vCenter Server Management Interface, the error message "Check the URL and try again" displays. The error message does not prevent you from using the functions within the Update panel, and you can view, stage, and install any available updates.

Workaround: None.

Patching witness or passive nodes of environments with VMware vCenter Server High Availability enabled might fail

In environments with vCenter Server High Availability enabled, patching a witness or passive node might fail with a message similar to:

`RuntimeError: unidentifiable C++ exception.`

Workaround: Deactivate vCenter Server High Availability. Apply patches to your vCenter Server system. Re-enable vCenter Server High Availability.

After patching your vCenter Server system to vCenter Server 7.0.0a, the TLS version of the VC Storage Clients might revert to the default

If you have a TLS configuration for the VC Storage Clients service different from the default TLS 1.2 only, the TLS version might revert to the default after patching your vCenter Server system to vCenter Server 7.0.0a.

Workaround: Use the TLS Configuration utility to enable or deactivate TLS versions on your vCenter Server system after the update.

After updating your system to vCenter Server 7.0.0b, you see systemd core dump in the /var/core folder

After updating your system to vCenter Server 7.0.0b from either vCenter Server 7.0.0a or vCenter Server 7.0, in the `/var/core` folder you see systemd core dump, such as `core.systemd-journal.393` and `core.systemd-udevd.405`. The core dump is harmless and can be removed.

Workaround: None

After updating your vCenter Server system to 7.0.0b, the vCenter Server version is not updated in the Direct Console User Interface (DCUI)

After updating your system to vCenter Server 7.0.0b from vCenter Server 7.0.0a or vCenter Server 7.0, you still see the previous vCenter Server version in the DCUI.

Workaround: After you complete the update, to refresh the vCenter Server version, in the appliance shell, run the command `/usr/lib/applmgmt/dcui/notify`.

Update Planner fails with error Configured repository is not accessible due to network connectivity or incorrect URL

If you use Update Planner, which is part of vSphere Lifecycle Manager used to facilitate vCenter Server updates, you might see the following error in the vSphere Client:

`Configured repository is not accessible due to network connectivity or incorrect URL. Verify the repository settings.`

The issue occurs when you use a custom local repository, such as `https:///uploads/dpe/` or a DBC path, to store the extracted . If the custom repository for URL-based patching has an authentication policy, Update Planner might not be able to fetch the list of available updates.

Workaround: Configure the custom repository such that authentication is not needed to access the custom repository URL.

After upgrading to vCenter Server 7.0.0b, you see vSphere HA errors on vSphere Lifecycle Manager Image based clusters

After upgrading to vCenter Server 7.0.0b, on vSphere Lifecycle Manager Image based clusters that are configured with vSphere HA, you might see error messages about the vSphere HA configuration after logging in for the first time to the environment. In the vSphere Client, you see messages such as:

`Cannot complete the configuration of the vSphere HA agent on the host.` or

`Applying HA VIBs on the cluster encountered a failure.`

The issue occurs because exports of the image depot might take long and cause a timeout of the task. In the `/storage/log/vmware/vmware-updatemgr/vum-server/vmware-vum-server.log` you see this message: `Export taking too long (Failure case)`

Workaround: This is a transient issue that resolves in 10 minutes after the vCenter Server is up and running. The issue does not affect any functionality. vSphere HA on the affected clusters operates as expected. All operations related to virtual machines, such as power on and migration, work across the vSphere HA-enabled clusters while this error recovery is still in progress.

You do not see a precheck error when patching to vCenter Server 7.0 Update 3d by using CLI

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3d and later add an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. In some cases, if such hosts exist in your system, patching from a vCenter Server version earlier than 7.0 Update 3 to a version later than 7.0 Update 3 by using CLI might fail with the error `Installation failed. Retry to resume from the current state. Or please collect the VC support bundle.` . However, instead of this error, you must see the precheck error message.

Workaround: If you do not see the precheck error and patching your system to vCenter Server 7.0 Update 3d fails, make sure all ESXi hosts are upgraded to ESXi 7.0 Update 3d, by using either a baseline created from an ISO or a single image, before upgrading vCenter Server. Do not use patch baselines based on the rollup bulletin. You can find additional debug log information at `/var/log/vmware/applmgmt` . For more details, see VMware knowledge base articles 87319 and 86447.

Security Features Issues

Encrypted virtual machine fails to power on when HA-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled HA on the Trusted Cluster and one or more hosts in the cluster fails attestation, an encrypted virtual machine cannot power on.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Encrypted virtual machine fails to power on when DRS-enabled Trusted Cluster contains an unattested host

In VMware® vSphere Trust Authority™, if you have enabled DRS on the Trusted Cluster and one or more hosts in the cluster fails attestation, DRS might try to power on an encrypted virtual machine on an unattested host in the cluster. This operation puts the virtual machine in a locked state.

Workaround: Either remove or remediate all hosts that failed attestation from the Trusted Cluster.

Migrating or cloning encrypted virtual machines across vCenter Server instances fails when attempting to do so using the vSphere Client

If you try to migrate or clone an encrypted virtual machine across vCenter Server instances using the vSphere Client, the operation fails with the following error message: "The operation is not allowed in the current state."

Workaround: You must use the vSphere APIs to migrate or clone encrypted virtual machines across vCenter Server instances.

Networking Issues

PR3304411: After batch cloning and customizing Windows virtual machines, the VMs network might not be configured

When cloning Windows VMs in bulk, a MAC address conflict might occur, causing vCenter to reassign new MAC addresses to the VMs. As a result, the guest customization process fails to configure properly the VMs network because it cannot match the original MAC address to the corresponding network card.

This issue is resolved in this release.

When you use the VMware Remote Console, the envoy service might intermittently fail

An issue with the envoy service specific to the VMware Remote Console might lead to intermittent failures of the service. As a result, the vCenter Server Management Interface or vCenter Server APIs might also become unavailable.

Workaround: Use the vSphere Client as an alternative to the VMware Remote Console.

Reduced throughput in networking performance on Intel 82599/X540/X550 NICs

The new queue-pair feature added to ixgben driver to improve networking performance on Intel 82599EB/X540/X550 series NICs might reduce throughput under some workloads in vSphere 7.0 as compared to vSphere 6.7.

Workaround: To achieve the same networking performance as vSphere 6.7, you can deactivate the queue-pair with a module parameter. To deactivate the queue-pair, run the command:

```
# esxcli system module parameters set -p "QPair=0,0,0,0..." -m ixgben
```

After running the command, reboot.

If you try to deactivate vSphere with Tanzu on a vSphere cluster, the operation stops with an error

If some virtual machines outside of a Supervisor Cluster reside on any of the NSX segment port groups on the cluster, the cleanup script cannot delete such ports and deactivate vSphere with Tanzu on the cluster. In the vSphere Client, you see the error `Cleanup requests to NSX Manager failed` and the operation stops at `Removing` status. In the `/var/log/vmware/wcp/wcpsvc.log` file, you see an error message such as

```
Segment path=[...] has x VMs or VIFs attached. Disconnect all VMs and VIFs before deleting a segment.
```

Workaround: Delete the virtual machines indicated in the `/var/log/vmware/wcp/wcpsvc.log` file from the segment. Wait for the operation to restore.

After upgrading to NSX 6.4.7, when a static IPv6 address is assigned to workload VMs on an IPv6 network, the VMs are unable to ping the IPv6 gateway interface of the edge

This issue occurs after upgrading the vSphere Distributed Switches from 6.x to 7.0.

Workaround 1:

Select the VDS where all the hosts are connected, go to the **Edit** setting, and under **Multicast** option switch to basic.

Workaround 2:

Add the following rules on the edge firewall:

Ping allow rule.

Multicast Listener Discover (MLD) allow rule, which are icmp6, type 130 (v1) and type 143 (v2).

High throughput virtual machines may experience degradation in network performance when Network I/O Control (NetIOC) is enabled

Virtual machines requiring high network throughput can experience throughput degradation when upgrading from vSphere 6.7 to vSphere 7.0 with NetIOC enabled.

Workaround: Adjust the `ethernetx.ctxPerDev` setting to enable multiple worlds.

IPv6 traffic fails to pass through VMkernel ports using IPsec

When you migrate VMkernel ports from one port group to another, IPv6 traffic does not pass through VMkernel ports using IPsec.

Workaround: Remove the IPsec security association (SA) from the affected server, and then reapply the SA. To learn how to set and remove an IPsec SA, see the *vSphere Security* documentation.

Higher ESX network performance with a portion of CPU usage increase

ESX network performance may increase with a portion of CPU usage.

Workaround: Remove and add the network interface with only 1 rx dispatch queue. For example:

```
esxcli network ip interface remove --interface-name=vmk1
esxcli network ip interface add --interface-name=vmk1 --num-rxqueue=1
```

VM might lose Ethernet traffic after hot-add, hot-remove or storage vMotion

A VM might stop receiving Ethernet traffic after a hot-add, hot-remove or storage vMotion. This issue affects VMs where the uplink of the VNIC has SR-IOV enabled. PVRDMA virtual NIC exhibits this issue when the uplink of the virtual network is a Mellanox RDMA capable NIC and RDMA namespaces are configured.

Workaround: You can hot-remove and hot-add the affected Ethernet NICs of the VM to restore traffic. On Linux guest operating systems, restarting the network might also resolve the issue. If these workarounds have no effect, you can reboot the VM to restore network connectivity.

Change of IP address for a VCSA deployed with static IP address requires that you create the DNS records in advance

With the introduction of the DDNS, the DNS record update only works for VCSA deployed with DHCP configured networking. While changing the IP address of the vCenter server via VAMI, the following error is displayed:

The specified IP address does not resolve to the specified hostname.

Workaround: There are two possible workarounds.

1. Create an additional DNS entry with the same FQDN and desired IP address. Log in to the VAMI and follow the steps to change the IP address.

2. Log in to the VCSA using ssh. Execute the following script:
   `./opt/vmware/share/vami/vami_config_net`
   Use option 6 to change the IP adddress of eth0. Once changed, execute the following script:
   `./opt/likewise/bin/lw-update-dns`
   Restart all the services on the VCSA to update the IP information on the DNS server.

It may take several seconds for the NSX Distributed Virtual Port Group (NSX DVPG) to be removed after deleting the corresponding logical switch in NSX Manager.

As the number of logical switches increases, it may take more time for the NSX DVPG in vCenter Server to be removed after deleting the corresponding logical switch in NSX Manager. In an environment with 12000 logical switches, it takes approximately 10 seconds for an NSX DVPG to be deleted from vCenter Server.

Workaround: None.

Hostd runs out of memory and fails if a large number of NSX Distributed Virtual port groups are created.

In vSphere 7.0, NSX Distributed Virtual port groups consume significantly larger amounts of memory than opaque networks. For this reason, NSX Distributed Virtual port groups can not support the same scale as an opaque network given the same amount of memory.

Workaround:To support the use of NSX Distributed Virtual port groups, increase the amount of memory in your ESXi hosts. If you verify that your system has adequate memory to support your VMs, you can directly increase the memory of `hostd` using the following command.

```
localcli --plugin-dir /usr/lib/vmware/esxcli/int/ sched group setmemconfig --group-path
host/vim/vmvisor/hostd --units mb --min 2048 --max 2048
```

Note that this will cause `hostd` to use memory normally reserved for your environment's VMs. This may have the affect of reducing the number of VMs your ESXi host can support.

DRS may incorrectly launch vMotion if the network reservation is configured on a VM

If the network reservation is configured on a VM, it is expected that DRS only migrates the VM to a host that meets the specified requirements. In a cluster with NSX transport nodes, if some of the transport nodes join the transport zone by NSX-T Virtual Distributed Switch (N-VDS), and others by vSphere Distributed Switch (VDS) 7.0, DRS may incorrectly launch vMotion. You might encounter this issue when:

- The VM connects to an NSX logical switch configured with a network reservation.
- Some transport nodes join transport zone using N-VDS, and others by VDS 7.0, or, transport nodes join the transport zone through different VDS 7.0 instances.

Workaround: Make all transport nodes join the transport zone by N-VDS or the same VDS 7.0 instance.

When adding a VMkernel NIC (vmknic) to an NSX portgroup, vCenter Server reports the error "Connecting VMKernel adapter to a NSX Portgroup on a Stateless host is not a supported operation. Please use Distributed Port Group instead."

- For stateless ESXi on Distributed Virtual Switch (VDS), the vmknic on a NSX port group is blocked. You must instead use a Distributed Port Group.
- For stateful ESXi on VDS, vmknic on NSX port group is supported, but vSAN may have an issue if it is using vmknic on a NSX port group.

Workaround: Use a Distributed Port Group on the same VDS.

Enabling SRIOV from vCenter for QLogic 4x10GE QL41164HFCU CNA might fail

If you navigate to the **Edit Settings** dialog for physical network adapters and attempt to enable SR-IOV, the operation might fail when using QLogic 4x10GE QL41164HFCU CNA. Attempting to enable SR-IOV might lead to a network outage of the ESXi host.

Workaround: Use the following command on the ESXi host to enable SRIOV:

```
esxcfg-module
```

Storage Issues

VMFS datastores are not mounted automatically after disk hot remove and hot insert on HPE Gen10 servers with SmartPQI controllers

When SATA disks on HPE Gen10 servers with SmartPQI controllers without expanders are hot removed and hot inserted back to a different disk bay of the same machine, or when multiple disks are hot removed and hot inserted back in a different order, sometimes a new local name is assigned to the disk. The VMFS datastore on that disk appears as a snapshot and will not be mounted back automatically because the device name has changed.

Workaround: None. SmartPQI controller does not support unordered hot remove and hot insert operations.

ESXi might terminate I/O to NVMeOF devices due to errors on all active paths

Occasionally, all active paths to NVMeOF device register I/O errors due to link issues or controller state. If the status of one of the paths changes to Dead, the High Performance Plug-in (HPP) might not select another path if it shows high volume of errors. As a result, the I/O fails.

Workaround: Deactivate the configuration option **/Misc/HppManageDegradedPaths** to unblock the I/O.

VOMA check on NVMe based VMFS datastores fails with error

VOMA check is not supported for NVMe based VMFS datastores and will fail with the error:

```
ERROR: Failed to reserve device. Function not implemented
```

Example:

```
# voma -m vmfs -f check -d /vmfs/devices/disks/: <partition#>
Running VMFS Checker version 2.1 in check mode
Initializing LVM metadata, Basic Checks will be done

Checking for filesystem activity
Performing filesystem liveness check..|Scanning for VMFS-6 host activity (4096 bytes/HB, 1024 HBs).
ERROR: Failed to reserve device. Function not implemented
Aborting VMFS volume check
VOMA failed to check device : General Error
```

Workaround: None. If you need to analyse VMFS metadata, collect it using the `-l` option, and pass to VMware customer support. The command for collecting the dump is:

```
voma -l -f dump -d /vmfs/devices/disks/:<partition#>
```

Using the VM reconfigure API to attach an encrypted First Class Disk to an encrypted virtual machine might fail with error

If an FCD and a VM are encrypted with different crypto keys, your attempts to attach the encrypted FCD to the encrypted VM using the `VM reconfigure API` might fail with the error message:

```
Cannot decrypt disk because key or password is incorrect.
```

Workaround: Use the `attachDisk API` rather than the `VM reconfigure API` to attach an encrypted FCD to an encrypted VM.

ESXi host might get in non responding state if a non-head extent of its spanned VMFS datastore enters the Permanent Device Loss (PDL) state

This problem does not occur when a non-head extent of the spanned VMFS datastore fails along with the head extent. In this case, the entire datastore becomes inaccessible and no longer allows I/Os.

In contrast, when only a non-head extent fails, but the head extent remains accessible, the datastore heartbeat appears to be normal. And the I/Os between the host and the datastore continue. However, any I/Os that depend on the failed non-head extent start failing as well. Other I/O transactions might accumulate while waiting for the failing I/Os to resolve, and cause the host to enter the non responding state.

Workaround: Fix the PDL condition of the non-head extent to resolve this issue.

After recovering from APD or PDL conditions, VMFS datastore with enabled support for clustered virtual disks might remain inaccessible

You can encounter this problem only on datastores where the clustered virtual disk support is enabled. When the datastore recovers from an All Paths Down (APD) or Permanent Device Loss (PDL) condition, it remains inaccessible. The VMkernel log might show multiple `SCSI3 reservation conflict` messages similar to the following:

```
2020-02-18T07:41:10.273Z cpu22:1001391219)ScsiDeviceIO: vm 1001391219:
SCSIDeviceCmdCompleteCB:2972: Reservation conflict retries 544 for command 0x45ba814b8340
(op: 0x89) to device "naa.624a9370b97601e346f64ba900024d53"
```

The problem can occur because the ESXi host participating in the cluster loses SCSI reservations for the datastore and cannot always reacquire them automatically after the datastore recovers.

Workaround: Manually register the reservation using the following command:

```
vmkfstools -L registerkey /vmfs/devices/disks/<device name>
```

where the `<device name>` is the name of the device on which the datastore is created.

Virtual NVMe Controller is the default disk controller for Windows 10 guest operating systems

The Virtual NVMe Controller is the default disk controller for the following guest operating systems when using Hardware Version 15 or later:

Windows 10

Windows Server 2016

Windows Server 2019

Some features might not be available when using a Virtual NVMe Controller. For more information, see https://kb.vmware.com/s/article/2147714

Note: Some clients use the previous default of LSI Logic SAS. This includes ESXi host client and PowerCLI.

Workaround: If you need features not available on Virtual NVMe, switch to VMware Paravirtual SCSI (PVSCSI) or LSI Logic SAS. For information on using VMware Paravirtual SCSI (PVSCSI), see https://kb.vmware.com/s/article/1010398

After an ESXi host upgrade to vSphere 7.0, presence of duplicate core claim rules might cause unexpected behavior

Claim rules determine which multipathing plugin, such as NMP, HPP, and so on, owns paths to a particular storage device. ESXi 7.0 does not support duplicate claim rules. However, the ESXi 7.0 host does not alert you if you add duplicate rules

to the existing claim rules inherited through an upgrade from a legacy release. As a result of using duplicate rules, storage devices might be claimed by unintended plugins, which can cause unexpected outcome.

Workaround: Do not use duplicate core claim rules. Before adding a new claim rule, delete any existing matching claim rule.

A CNS query with the compliance status filter set might take unusually long time to complete

The CNS QueryVolume API enables you to obtain information about the CNS volumes, such as volume health and compliance status. When you check the compliance status of individual volumes, the results are obtained quickly. However, when you invoke the CNS QueryVolume API to check the compliance status of multiple volumes, several tens or hundreds, the query might perform slowly.

Workaround: Avoid using bulk queries. When you need to get compliance status, query one volume at a time or limit the number of volumes in the query API to 20 or fewer. While using the query, avoid running other CNS operations to get the best performance.

New Deleted CNS volumes might temporarily appear as existing in the CNS UI

After you delete an FCD disk that backs a CNS volume, the volume might still show up as existing in the CNS UI. However, your attempts to delete the volume fail. You might see an error message similar to the following:

```
The object or item referred to could not be found.
```

Workaround: The next full synchronization will resolve the inconsistency and correctly update the CNS UI.

New Under certain circumstances, while a CNS operation fails, the task status appears as successful in the vSphere Client

This might occur when, for example, you use an incompliant storage policy to create a CNS volume. The operation fails, while the vSphere Client shows the task status as successful.

Workaround: The successful task status in the vSphere Client does not guarantee that the CNS operation succeeded. To make sure the operation succeeded, verify its results.

New Unsuccessful delete operation for a CNS persistent volume might leave the volume undeleted on the vSphere datastore

This issue might occur when the CNS Delete API attempts to delete a persistent volume that is still attached to a pod. For example, when you delete the Kubernetes namespace where the pod runs. As a result, the volume gets cleared from CNS and the CNS query operation does not return the volume. However, the volume continues to reside on the datastore and cannot be deleted through the repeated CNS Delete API operations.

Workaround: None.

vCenter Server and vSphere Client Issues

PR 3262556: vCenter upgrade fails with "VP last sync time not updated after waiting for 5 minutes after vCenter update"

In rare cases, during a vCenter upgrade, a race condition between vSphere API for Storage Awareness (VASA) providers might cause the upgrade to fail. In the `pod-service.log` file, you see an error such as `vSAN VP last sync time not updated after waiting for 5 minutes after vCenter update.`

This issue is resolved in this release. The fix prevents the race condition.

You do not see the VLAN ID in the port properties page of a VMkernel network adapter in the vSphere Client

In the vSphere Client, when you follow the path **Host > Add Networking**, after you select a VMkernel network adapter and an existing standard switch, in the **Port properties** page you might not see the VLAD ID. The issue occurs because the VLAN ID component is part of the `network-ui` module, which is lazy loaded and needs a trigger to refresh.

Workaround: Go to **Host > Configure > Networking > Virtual Switches** to trigger the loading of the `network ui` module and the VLAD ID appears.

Vendor providers go offline after a PNID change

When you change the vCenter IP address (PNID change), the registered vendor providers go offline.

Workaround: Re-register the vendor providers.

Cross vCenter migration of a virtual machine fails with an error

When you use cross vCenter vMotion to move a VM's storage and host to a different vCenter server instance, you might receive the error `The operation is not allowed in the current state.`

This error appears in the UI wizard after the Host Selection step and before the Datastore Selection step, in cases where the VM has an assigned storage policy containing host-based rules such as encryption or any other IO filter rule.

Workaround: Assign the VM and its disks to a storage policy without host-based rules. You might need to decrypt the VM if the source VM is encrypted. Then retry the cross vCenter vMotion action.

Storage Sensors information in Hardware Health tab shows incorrect values on vCenter UI, host UI, and MOB

When you navigate to **Host > Monitor > Hardware Health > Storage Sensors** on vCenter UI, the storage information displays either incorrect or unknown values. The same issue is observed on the host UI and the MOB path `"runtime.hardwareStatusInfo.storageStatusInfo"` as well.

Workaround: None.

vSphere UI host advanced settings shows the current product locker location as empty with an empty default

vSphere UI host advanced settings shows the current product locker location as empty with an empty default. This is inconsistent as the actual product location `symlink` is created and valid. This causes confusion to the user. The default cannot be corrected from UI.

Workaround: User can use the esxcli command on the host to correct the current product locker location default as below.

1. Remove the existing Product Locker Location setting with: `"esxcli system settings advanced remove -o ProductLockerLocation"`

2. Re-add the Product Locker Location setting with the appropriate default:

2.a. If the ESXi is a full installation, the default value is `"/locker/packages/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/locker/packages/vmtoolsRepo"`

2.b. If the ESXi is a PXEboot configuration such as autodeploy, the default value is: `"/vmtoolsRepo" export PRODUCT_LOCKER_DEFAULT="/vmtoolsRepo"`

Run the following command to automatically figure out the location: `export PRODUCT_LOCKER_DEFAULT=`readlink /productLocker``

Add the setting: `esxcli system settings advanced add -d "Path to VMware Tools repository" -o ProductLockerLocation -t string -s $PRODUCT_LOCKER_DEFAULT`

You can combine all the above steps in step 2 by issuing the single command:

```
esxcli system settings advanced add -d "Path to VMware Tools repository" -o
ProductLockerLocation -t string -s `readlink /productLocker`
```

Skyline Health page displays garbage characters

In the vSphere Client, when you navigate to vCenter Server or select an ESXi host in the vSphere Client navigator and click Monitor > Skyline Health, the page displays garbage characters in the following locales: Korean, Japanese, German and French.

Workaround: Switch to English locale.

Virtual Machine Management Issues

You cannot add or modify an existing network adapter on a virtual machine

If you try to add or modify an existing network adapter on a virtual machine, the Reconfigure Virtual Machine task might fail with an error such as `Cannot complete operation due to concurrent modification by another operation` in the vSphere Client. In the `/var/log/hostd.log` file of the ESXi host where the virtual machine runs, you see logs such as:

```
2020-07-28T07:47:31.621Z verbose hostd[2102259] [Originator@6876 sub=Vigor.Vmsvc.vm:/vmfs/volumes/vsan:526bc94351cf8f42-41153841cab2f9d9/bad71f5f-d85e-a276-4cf6-246e965d7154/interop_l2vpn_vmotion_VM_1.vmx] NIC: connection control message: Failed to connect virtual device 'ethernet0'.
```

In the `vpxa.log` file, you see entries similar to: `2020-07-28T07:47:31.941Z info vpxa[2101759] [Originator@6876 sub=Default opID=opId-59f15-19829-91-01-ed] [VpxLRO] -- ERROR task-138 -- vm-13 -- vim.VirtualMachine.reconfigure: vim.fault.GenericVmConfigFault:`

Workaround: For each ESXi host in your cluster do the following:

1. Connect to the ESXi host by using SSH and run the command
   `esxcli system module parameters set -a -p dvfiltersMaxFilters=8192 -m dvfilter`
2. Put the ESXi host in Maintenance Mode.
3. Reboot the ESXi host.

For more information, see VMware knowledge base article 80399.

ESXi 6.5 hosts with AMD Opteron Generation 3 (Greyhound) processors cannot join Enhanced vMotion Compatibility (EVC) AMD REV E or AMD REV F clusters on a vCenter Server 7.0 Update 1 system

In vCenter Server 7.0 Update 1, vSphere cluster services, such as vSphere DRS and vSphere HA, run on ESX agent virtual machines to make the services functionally independent of vCenter Server. However, the CPU baseline for AMD processors of the ESX agent virtual machines have POPCNT SSE4A instructions, which prevents ESXi 6.5 hosts with AMD Opteron Generation 3 (Greyhound) processors to enable EVC mode AMD REV E and AMD REV F on a vCenter Server 7.0 Update 1 system.

Workaround: None

The postcustomization section of the customization script runs before the guest customization

When you run the guest customization script for a Linux guest operating system, the `precustomization` section of the customization script that is defined in the customization specification runs before the guest customization and the `postcustomization` section runs after that. If you enable Cloud-Init in the guest operating system of a virtual machine, the `postcustomization` section runs before the customization due to a known issue in Cloud-Init.

Workaround: Deactivate Cloud-Init and use the standard guest customization.

Group migration operations in vSphere vMotion, Storage vMotion, and vMotion without shared storage fail with error

When you perform group migration operations on VMs with multiple disks and multi-level snapshots, the operations might fail with the error `com.vmware.vc.GenericVmConfigFault Failed waiting for data. Error 195887167. Connection closed by remote host, possibly due to timeout.`

Workaround: Retry the migration operation on the failed VMs one at a time.

Deploying an OVF or OVA template from a URL fails with a 403 Forbidden error

The URLs that contain an HTTP query parameter are not supported. For example, `http://webaddress.com?file=abc.ovf` or the Amazon pre-signed S3 URLs.

Workaround: Download the files and deploy them from your local file system.

Importing or deploying local OVF files containing non-ASCII characters in their name might fail with an error

When you import local `.ovf` files containing non-ASCII characters in their name, you might receive `400 Bad Request Error` . When you use such `.ovf` files to deploy a virtual machine in the vSphere Client, the deployment process stops at 0%. As a result, you might receive `400 Bad Request Error` or `500 Internal Server Error` .

Workaround:

1. Remove the non-ASCII characters from the `.ovf` and `.vmdk` file names.
   – To edit the `.ovf` file, open it with a text editor.
   – Search the non-ASCII `.vmdk` file name and change it to ASCII.
2. Import or deploy the saved files again.

New The third level of nested objects in a virtual machine folder is not visible

Perform the following steps:

1. Navigate to a data center and create a virtual machine folder.
2. In the virtual machine folder, create a nested virtual machine folder.
3. In the second folder, create another nested virtual machine, virtual machine folder, vApp, or VM Template.

As a result, from the VMs and Templates inventory tree you cannot see the objects in the third nested folder.

Workaround: To see the objects in the third nested folder, navigate to the second nested folder and select the VMs tab.

vSAN file services operations fail on vSphere Lifecycle Manager-enabled clusters

During a change in the state of an ESXi host, vSAN file services operations might fail on vSphere Lifecycle Manager-enabled clusters due to a race condition with the vSphere ESX Agent Manager (EAM). The problem happens during upgrades and operations, such as power on or power off, booting, or when the host exits maintenance or standby mode. The race condition occurs when an endpoint has been unavailable before the change of state of the ESXi host. In such cases, the EAM starts a remediation process that cannot be resolved and fails operations from other services, such as the vSAN file services.

Workaround: Restart the vSphere ESX Agent Manager.

vSphere HA and Fault Tolerance Issues

VMs in a cluster might be orphaned after recovering from storage inaccessibility such as a cluster wide APD

Some VMs might be in orphaned state after cluster wide APD recovers, even if HA and VMCP are enabled on the cluster.

This issue might be encountered when the following conditions occur simultaneously:

- All hosts in the cluster experience APD and do not recover until VMCP timeout is reached.

- HA primary initiates failover due to APD on a host.
- Power on API during HA failover fails due to one of the following:
  - APD across the same host
  - Cascading APD across the entire cluster
  - Storage issues
  - Resource unavailability
- FDM unregistration and VCs steal VM logic might initiate during a window where FDM has not unregistered the failed VM and VC's host synchronization responds that multiple hosts are reporting the same VM. Both FDM and VC unregister the different registered copies of the same VM from different hosts, causing the VM to be orphaned.

Workaround: You must unregister and reregister the orphaned VMs manually within the cluster after the APD recovers.

If you do not manually reregister the orphaned VMs, HA attempts failover of the orphaned VMs, but it might take between 5 to 10 hours depending on when APD recovers.

The overall functionality of the cluster is not affected in these cases and HA will continue to protect the VMs. This is an anomaly in what gets displayed on VC for the duration of the problem.

vSphere Lifecycle Manager Issues

vSphere Lifecycle Manager and vSAN File Services cannot be simultaneously enabled on a vSAN cluster in vSphere 7.0 release

If vSphere Lifecycle Manager is enabled on a cluster, vSAN File Services cannot be enabled on the same cluster and vice versa. In order to enable vSphere Lifecycle Manager on a cluster, which has VSAN File Services enabled already, first deactivate vSAN File Services and retry the operation. Please note that if you transition to a cluster that is managed by a single image, vSphere Lifecycle Manager cannot be deactivated on that cluster.

Workaround: None.

You cannot edit the VMware vSphere Lifecycle Manager Update Download scheduled task

In the vSphere Client, when you navigate to a vCenter Server instance and select **Scheduled Tasks** under the **Configure** tab, if you select the **VMware vSphere Lifecycle Manager Update Download** task and click **Edit**, you cannot modify the existing settings.

Workaround: You can edit the **VMware vSphere Lifecycle Manager Update Download** task by following the steps in the topic Configure the vSphere Lifecycle Manager Automatic Download Task.

When a hardware support manager is unavailable, vSphere High Availability (HA) functionality is impacted

If hardware support manager is unavailable for a cluster that you manage with a single image, where a firmware and drivers addon is selected and vSphere HA is enabled, the vSphere HA functionality is impacted. You may experience the following errors.

- Configuring vSphere HA on a cluster fails.
- Cannot complete the configuration of the vSphere HA agent on a host: `Applying HA VIBs on the cluster encountered a failure.`
- Remediating vSphere HA fails: `A general system error occurred: Failed to get Effective Component map.`
- Disabling vSphere HA fails: Delete Solution task failed. `A general system error occurred: Cannot find hardware support package from depot or hardware support manager.`

Workaround:

- If the hardware support manager is temporarily unavailable, perform the following steps.

1. Reconnect the hardware support manager to vCenter Server.
2. Select a cluster from the Hosts and Cluster menu.
3. Select the Configure tab.
4. Under Services, click vSphere Availability.
5. Re-enable vSphere HA.

- If the hardware support manager is permanently unavailable, perform the following steps.

1. Remove the hardware support manager and the hardware support package from the image specification
2. Re-enable vSphere HA.
3. Select a cluster from the Hosts and Cluster menu.
4. Select the Updates tab.
5. Click Edit .
6. Remove the firmware and drivers addon and click Save.
7. Select the Configure tab.
8. Under Services, click vSphere Availability.
9. Re-enable vSphere HA.

I/OFilter is not removed from a cluster after a remediation process in vSphere Lifecycle Manager

Removing I/OFilter from a cluster by remediating the cluster in vSphere Lifecycle Manager, fails with the following error message: `iofilter XXX already exists` . The iofilter remains listed as installed.

Workaround:

1. Call IOFilter API `UninstallIoFilter_Task` from the vCenter Server managed object (IoFilterManager).
2. Remediate the cluster in vSphere Lifecycle Manager.
3. Call IOFilter API `ResolveInstallationErrorsOnCluster_Task` from the vCenter Server managed object (IoFilterManager) to update the database.

While remediating a vSphere HA enabled cluster in vSphere Lifecycle Manager, disabling and re-enabling vSphere HA causes a vSphere HA error state

Disabling and re-enabling vSphere HA during remediation process of a cluster, may fail the remediation process due to vSphere HA health checks reporting that hosts don't have vSphere HA VIBs installed. You may see the following error message: `Setting desired image spec for cluster failed` .

Workaround: After the cluster remediation operation has finished, deactivate and re-enable vSphere HA for the cluster.

Checking for recommended images in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the recommendation generation task could take more than an hour to finish or may appear to hang. The completion time for the recommendation task depends on the number of devices configured on each host and the number of image candidates from the depot that vSphere Lifecycle Manager needs to process before obtaining a valid image to recommend.

Workaround: None.

Checking for hardware compatibility in vSphere Lifecycle Manager has slow performance in large clusters

In large clusters with more than 16 hosts, the validation report generation task could take up to 30 minutes to finish or may appear to hang. The completion time depends on the number of devices configured on each host and the number of hosts configured in the cluster.

Workaround: None

Incomplete error messages in non-English languages are displayed, when remediating a cluster in vSphere Lifecycle Manager

You can encounter incomplete error messages for localized languages in the vCenter Server user interface. The messages are displayed, after a cluster remediation process in vSphere Lifecycle Manager fails. For example, your can observe the following error message.

The error message in English language: `Virtual machine 'VMC on DELL EMC -FileServer' that runs on cluster 'Cluster-1' reported an issue which prevents entering maintenance mode: Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

The error message in French language: `La VM « VMC on DELL EMC -FileServer », située sur le cluster « {Cluster-1} », a signalé un problème empêchant le passage en mode de maintenance : Unable to access the virtual machine configuration: Unable to access file[local-0] VMC on Dell EMC - FileServer/VMC on Dell EMC - FileServer.vmx`

Workaround: None.

When you convert a cluster that uses baselines to a cluster that uses a single image, a warning is displayed that vSphere HA VIBs will be removed

Converting a vSphere HA enabled cluster that uses baselines to a cluster that uses a single image, may result a warning message displaying that `vmware-fdm` component will be removed.

Workaround: This message can be ignored. The conversion process installs the `vmware-fdm` component.

If vSphere Update Manager is configured to download patch updates from the Internet through a proxy server, after upgrade to vSphere 7.0 that converts Update Manager to vSphere Lifecycle Manager, downloading patches from VMware patch repository might fail

In earlier releases of vCenter Server you could configure independent proxy settings for vCenter Server and vSphere Update Manager. After an upgrade to vSphere 7.0, vSphere Update Manager service becomes part of the vSphere Lifecycle Manager service. For the vSphere Lifecycle Manager service, the proxy settings are configured from the vCenter Server appliance settings. If you had configured Update Manager to download patch updates from the Internet through a proxy server but the vCenter Server appliance had no proxy setting configuration, after a vCenter Server upgrade to version 7.0, the vSphere Lifecycle Manager fails to connect to the VMware depot and is unable to download patches or updates.

Workaround: Log in to the vCenter Server Appliance Management Interface, https://*vcenter-server-appliance-FQDN-or-IP-address*:5480, to configure proxy settings for the vCenter Server appliance and enable vSphere Lifecycle Manager to use proxy.

If you use a Java client to review remediation tasks, you cannot extract the results from the remediation operations

If you use a Java client to review remediation tasks, extracting the results might fail with a `ConstraintValidationException` error. The issue occurs when an ESXi host fails to enter maintenance mode during the remediation and gets a status SKIPPED, but at the same time wrongly gets an In Progress flag for the consecutive remediation operations. This causes the `ConstraintValidationException` error on the Java Clients and you cannot extract the result of the remediation operation.

Workaround: Fix the underlying issues that prevent ESXi hosts to enter Maintenance Mode and retry the remediation operation.

The general vSphere Lifecycle Manager depot and local depots in Remote Office and Branch Office (ROBO) deployments might not be in sync

ROBO clusters that have limited or no access to the Internet or limited connectivity to vCenter Server can download an image from a depot that is local for them instead of accessing the vSphere Lifecycle Manager depot in vCenter Server. However, vSphere Lifecycle Manager generates software recommendations in the form of pre-validated images only on a central level and a recommended image content might not be available at a depot override.

Workaround: If you decide to use a recommended image, make sure the content between depot overrides and the central depot are in sync.

Cluster remediation by using the vSphere Lifecycle Manager might fail on ESXi hosts with enabled lockdown mode

If a cluster has ESXi hosts with enabled lockdown mode, remediation operations by using the vSphere Lifecycle Manager might skip such hosts. In the log files, you see messages such as `Host scan task failed` and `com.vmware.vcIntegrity.lifecycle.EsxImage.UnknownError An unknown error occurred while performing the operation.`.

Workaround: Add the root user to the exception list for lockdown mode and retry the cluster remediation.

You cannot use an ESXi image with OEM content to create clusters by using vSphere Lifecycle Manager workflows after an update

When you update an ESXi image with OEM content, for example Dell ESXi 7.0 Update 2a to Dell ESXi 7.0 Update 3d, some reserved VIBs, such that are present in the VMware base image but overridden by async VIBs packaged by the OEM, might be deleted. The same issue might occur after updating your system by using a non-critical baseline and then update to a higher version by using an ESXi image with OEM content. For example, if you update to 7.0 Update 2 by using a non-critical baseline and then update to 7.0 Update 3 by using a Dell ESXi 7.0 Update 3 image, reserved VIBs might also be deleted. As a result, you cannot use ESXi hosts with the updated version to create a vSphere Lifecycle Manager cluster managed by a single image. The operation fails and in the backtrace, you see errors such as:

```
2021-11-24T09:42:49Z lifecycle: 2101166: HostSeeding:956 ERROR Extract depot failed:
('VMW_bootbank_bnxtroce_216.0.58.0-23vmw.703.0.0.18644231', 'Failed to add reserved
VIB VMW_bootbank_bnxtroce_216.0.58.0-23vmw.703.0.0.18644231: not found in the reserved
VIB cache storage')2021-11-24T09:42:50Z lifecycle: 2101166: imagemanagerctl:373 ERROR
Extract depot failed.021-11-24T09:42:50Z lifecycle: 2101166: imagemanagerctl:152 ERROR
[ReservedVibExtractError] ('VMW_bootbank_bnxtroce_216.0.58.0-23vmw.703.0.0.18644231',
'Failed to add reserved VIB VMW_bootbank_bnxtroce_216.0.58.0-23vmw.703.0.0.18644231: not
found in the reserved VIB cache storage')
```

Workaround: Use interactive or scripted upgrade instead of vSphere Lifecycle Manager workflows.

After you upgrade to vCenter Server 7.0.0b, in the vSphere Lifecycle Manager home view in the vSphere Client, you do not see the Show only rollup updates toggle button

In vCenter Server 7.0.0b, you can use the **Show only rollup updates** toggle button to filter and select patches that you want to include in a baseline when you use the vSphere Lifecycle Manager.

The button is available in the **Updates** tab on the **Lifecycle Manager** pane, **Menu** > **Lifecycle Manager**, which is the vSphere Lifecycle Manager home view in the vSphere Client. The button is also available in the **Select Patches Manually** page on the **Baselines** tab in the **Create Baseline** wizard, which opens when you select **New** > **Baseline**.

However, the **Show only rollup updates** toggle button might not be visible after you upgrade to vCenter Server 7.0.0b.

Workaround: After an upgrade to vCenter Server 7.0.0b, restart the vSphere Client. For more information, see Start, Stop, and Restart Services.

The Show only rollup updates toggle button is always turned on when you open a tab in the vSphere Lifecycle Manager home view in the vSphere Client

In vCenter Server 7.0.0b, you can use the **Show only rollup updates** toggle button to filter and select patches that you want to include in a baseline when you use the vSphere Lifecycle Manager.

The button is available in the **Updates** tab on the **Lifecycle Manager** pane, **Menu** > **Lifecycle Manager**, which is the vSphere Lifecycle Manager home view in the vSphere Client. The button is also available in the **Select Patches Manually** page on the **Baselines** tab in the **Create Baseline** wizard, which opens when you select **New** > **Baseline**.

However, the toggle button appears always turned on when you navigate to either of the **Updates** tab or the **Select Patches Manually** page. Even if you turn off the button when navigating away from the tab or page, it appears still turned on the next time you open them.

Workaround: None

When you use the Update Planner, in the vSphere Client you might see Unexpected error occurred while fetching the updates

When you use Update Planner, which is part of vSphere Lifecycle Manager, used to facilitate vCenter Server updates, you might see the following error in the vSphere Client:

```
Unexpected error occurred while fetching the updates
```

The issue occurs when you use a custom HTTPS port that prevents you from running interoperability reports by using the vSphere Client.

Workaround: Manually invoke the API. For more details, see the vSphere Automation API.

Miscellaneous Issues

When applying a host profile with version 6.5 to a ESXi host with version 7.0, the compliance check fails

Applying a host profile with version 6.5 to a ESXi host with version 7.0, results in Coredump file profile reported as not compliant with the host.

Workaround: There are two possible workarounds.

1. When you create a host profile with version 6.5, set an advanced configuration option VMkernel.Boot.autoCreateDumpFile to false on the ESXi host.
2. When you apply an existing host profile with version 6.5, add an advanced configuration option VMkernel.Boot.autoCreateDumpFile in the host profile, configure the option to a fixed policy, and set value to false.

Cannot migrate container volume due to insufficient space

The Migrate volume dialog in vSphere Client considers the current size of container volumes and the free space available on the target datastores. If the free space of a datastore is less than the volume size, then you cannot select the datastore for migration. vSphere preserves the storage policy as it migrates the volume, but the file size of the volume might change depending on the destination datastore type and its supported features. The vSphere Client might show the datastore has insufficient space to perform the migration, even though enough space is available.

Workaround: None

The Actions drop-down menu does not contain any items when your browser is set to language different from English

When your browser is set to language different from English and you click the **Switch to New View** button from the virtual machine **Summary** tab of the vSphere Client inventory, the **Actions** drop-down menu in the **Guest OS** panel does not contain any items.

Workaround: Select the **Actions** drop-down menu on the top of the virtual machine page.

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit minor throughput degradation when Dynamic Receive Side Scaling (DYN_RSS) or Generic RSS (GEN_RSS) feature is turned on

Mellanox ConnectX-4 or ConnectX-5 native ESXi drivers might exhibit less than 5 percent throughput degradation when DYN_RSS and GEN_RSS feature is turned on, which is unlikely to impact normal workloads.

Workaround: You can deactivate DYN_RSS and GEN_RSS feature with the following commands:

```
# esxcli system module parameters set -m nmlx5_core -p "DYN_RSS=0 GEN_RSS=0"
# reboot
```

RDMA traffic between two VMs on the same host might fail in PVRDMA environment

In a vSphere 7.0 implementation of a PVRDMA environment, VMs pass traffic through the HCA for local communication if an HCA is present. However, loopback of RDMA traffic does not work on qedrntv driver. For instance, RDMA Queue Pairs running on VMs that are configured under same uplink port cannot communicate with each other.

In vSphere 6.7 and earlier, HCA was used for local RDMA traffic if SRQ was enabled. vSphere 7.0 uses HCA loopback with VMs using versions of PVRDMA that have SRQ enabled with a minimum of HW v14 using RoCE v2.

The current version of Marvell FastLinQ adapter firmware does not support loopback traffic between QPs of the same PF or port.

Workaround: Required support is being added in the out-of-box driver certified for vSphere 7.0. If you are using the inbox qedrntv driver, you must use a 3-host configuration and migrate VMs to the third host.

Unreliable Datagram traffic QP limitations in qedrntv driver

There are limitations with the Marvell FastLinQ qedrntv RoCE driver and Unreliable Datagram (UD) traffic. UD applications involving bulk traffic might fail with qedrntv driver. Additionally, UD QPs can only work with DMA Memory Regions (MR). Physical MRs or FRMR are not supported. Applications attempting to use physical MR or FRMR along with UD QP fail to pass traffic when used with qedrntv driver. Known examples of such test applications are `ibv_ud_pingpong` and `ib_send_bw`.

Standard RoCE and RoCEv2 use cases in a VMware ESXi environment such as iSER, NVMe-oF (RoCE) and PVRDMA are not impacted by this issue. Use cases for UD traffic are limited and this issue impacts a small set of applications requiring bulk UD traffic.

Marvell FastLinQ hardware does not support RDMA UD traffic offload. In order to meet the VMware PVRDMA requirement to support GSI QP, a restricted software only implementation of UD QP support was added to the qedrntv driver. The goal of the implementation is to provide support for control path GSI communication and is not a complete implementation of UD QP supporting bulk traffic and advanced features.

Since UD support is implemented in software, the implementation might not keep up with heavy traffic and packets might be dropped. This can result in failures with bulk UD traffic.

Workaround: Bulk UD QP traffic is not supported with qedrntv driver and there is no workaround at this time. VMware ESXi RDMA (RoCE) use cases like iSER, NVMe, RDMA and PVRDMA are unaffected by this issue.

Servers equipped with QLogic 578xx NIC might fail when frequently connecting or disconnecting iSCSI LUNs

If you trigger QLogic 578xx NIC iSCSI connection or disconnection frequently in a short time, the server might fail due to an issue with the qfle3 driver. This is caused by a known defect in the device's firmware.

Workaround: None.

ESXi might fail during driver unload or controller disconnect operation in Broadcom NVMe over FC environment

In Broadcom NVMe over FC environment, ESXi might fail during driver unload or controller disconnect operation and display an error message such as: `@BlueScreen: #PF Exception 14 in world 2098707:vmknvmeGener IP 0x4200225021cc addr 0x19`

Workaround: None.

ESXi does not display OEM firmware version number of i350/X550 NICs on some Dell servers

The inbox ixgben driver only recognizes firmware data version or signature for i350/X550 NICs. On some Dell servers the OEM firmware version number is programmed into the OEM package version region, and the inbox ixgben driver does not read this information. Only the 8-digit firmware signature is displayed.

Workaround: To display the OEM firmware version number, install async ixgben driver version 1.7.15 or later.

X710 or XL710 NICs might fail in ESXi

When you initiate certain destructive operations to X710 or XL710 NICs, such as resetting the NIC or manipulating VMKernel's internal device tree, the NIC hardware might read data from non-packet memory.

Workaround: Do not reset the NIC or manipulate vmkernel internal device state.

NVMe-oF does not guarantee persistent VMHBA name after system reboot

NVMe-oF is a new feature in vSphere 7.0. If your server has a USB storage installation that uses vmhba30+ and also has NVMe over RDMA configuration, the VMHBA name might change after a system reboot. This is because the VMHBA name assignment for NVMe over RDMA is different from PCIe devices. ESXi does not guarantee persistence.

Workaround: None.

Backup fails for vCenter database size of 300 GB or greater

If the vCenter database size is 300 GB or greater, the file-based backup will fail with a timeout. The following error message is displayed: `Timeout! Failed to complete in 72000 seconds`

Workaround: None.

A restore of vCenter Server 7.0 which is upgraded from vCenter Server 6.x with External Platform Services Controller to vCenter Server 7.0 might fail

When you restore a vCenter Server 7.0 which is upgraded from 6.x with External Platform Services Controller to vCenter Server 7.0, the restore might fail and display the following error: `Failed to retrieve appliance storage list`

Workaround: During the first stage of the restore process, increase the storage level of the vCenter Server 7.0. For example if the vCenter Server 6.7 External Platform Services Controller setup storage type is small, select storage type large for the restore process.

Enabled SSL protocols configuration parameter is not configured during a host profile remediation process

`Enabled SSL protocols` configuration parameter is not configured during a host profile remediation and only the system default protocol `tlsv1.2` is enabled. This behavior is observed for a host profile with version 7.0 and earlier in a vCenter Server 7.0 environment.

Workaround: To enable TLSV 1.0 or TLSV 1.1 SSL protocols for SFCB, log in to an ESXi host by using SSH, and run the following ESXCLI command: `esxcli system wbem -P <protocol_name>`

Unable to configure Lockdown Mode settings by using Host Profiles

Lockdown Mode cannot be configured by using a security host profile and cannot be applied to multiple ESXi hosts at once. You must manually configure each host.

Workaround: In vCenter Server 7.0, you can configure Lockdown Mode and manage Lockdown Mode exception user list by using a security host profile.

When a host profile is applied to a cluster, Enhanced vMotion Compatibility (EVC) settings are missing from the ESXi hosts

Some settings in the VMware config file `/etc/vmware/config` are not managed by Host Profiles and are blocked, when the config file is modified. As a result, when the host profile is applied to a cluster, the EVC settings are lost, which causes loss of EVC functionalities. For example, unmasked CPUs can be exposed to workloads.

Workaround: Reconfigure the relevant EVC baseline on cluster to recover the EVC settings.

Using a host profile that defines a core dump partition in vCenter Server 7.0 results in an error

In vCenter Server 7.0, configuring and managing a core dump partition in a host profile is not available. Attempting to apply a host profile that defines a core dump partition, results in the following error: `No valid coredump partition found.`

Workaround: None. In vCenter Server 7.0., Host Profiles supports only file-based core dumps.

You cannot paste by right clicking in the vi editor

If you use the vi text editor on a vCenter Server Appliance instance, you cannot paste previously copied content by right clicking. Instead, the vi editor changes mode to Visual.

Workaround: From the vCenter Server Appliance shell, run the command`/usr/bin/sed -i.bak -E '2alet skip_defaults_vim=1' /etc/vimrc.`

HTTP requests from certain libraries to vSphere might be rejected

The HTTP reverse proxy in vSphere 7.0 enforces stricter standard compliance than in previous releases. This might expose pre-existing problems in some third-party libraries used by applications for SOAP calls to vSphere.

If you develop vSphere applications that use such libraries or include applications that rely on such libraries in your vSphere stack, you might experience connection issues when these libraries send HTTP requests to VMOMI. For example, HTTP requests issued from vijava libraries can take the following form:

```
POST /sdk HTTP/1.1
SOAPAction
Content-Type: text/xml; charset=utf-8
User-Agent: Java/1.8.0_221
```

The syntax in this example violates an HTTP protocol header field requirement that mandates a colon after SOAPAction. Hence, the request is rejected in flight.

Workaround: Developers leveraging noncompliant libraries in their applications can consider using a library that follows HTTP standards instead. For example, developers who use the vijava library can consider using the latest version of the yavijava library instead.

SNMP dynamic firewall ruleset is modified by Host Profiles during a remediation process

The SNMP firewall ruleset is a dynamic state, which is handled during runtime. When a host profile is applied, the configuration of the ruleset is managed simultaneously by Host Profiles and SNMP, which can modify the firewall settings unexpectedly.

Workaround: There are two possible workarounds.

- To allow the ruleset to manage itself dynamically, exclude the SNMP firewall ruleset option in the configuration of the host profile.

- To proceed with the double management of the ruleset, when needed, correct the firewall ruleset state.

You might see a dump file when using Broadcom driver lsi_msgpt3, lsi_msgpt35 and lsi_mr3

When using the lsi_msgpt3, lsi_msgpt35 and lsi_mr3 controllers, there is a potential risk to see dump file lsuv2-lsi-drivers-plugin-util-zdump. There is an issue when exiting the storelib used in this plugin utility. There is no impact on ESXi operations, you can ignore the dump file.

Workaround: You can safely ignore this message. You can remove the lsuv2-lsi-drivers-plugin with the following command:

```
esxcli software vib remove -n lsuv2-lsiv2-drivers-plugin
```

You might see reboot is not required after configuring SR-IOV of a PCI device in vCenter, but device configurations made by third party extensions might be lost and require reboot to be re-applied.

In ESXi 7.0, SR-IOV configuration is applied without a reboot and the device driver is reloaded. ESXi hosts might have third party extensions perform device configurations that need to run after the device driver is loaded during boot. A reboot is required for those third party extensions to re-apply the device configuration.

Workaround: You must reboot after configuring SR-IOV to apply third party device configurations.

You see black or grey zones in the background of a parent window in the Direct Console User Interface (DCUI) after a child window closes

In the DCUI, when you close a child window by pressing the ESC or Enter keys, or the **Cancel** or **OK** buttons, the parent window appearance might change. The background color changes to grey or black for some part of the parent window. However, all required information from the DCUI is properly displayed and all operations performed in the DCUI complete successfully.

Workaround: Wait for 1 minute without refreshing the current window in the DCUI or pressing any key.

Backup Issues

If you use the NFS and SMB protocols for file-based backup of vCenter Server, the backup fails after an update from vCenter Server 7.x to vCenter Server 7.0 Update 1

If you use the Network File System (NFS) and Server Message Block (SMB) protocols for file-based backup of vCenter Server, the backup fails after an update from an earlier version of vCenter Server 7.x to vCenter Server 7.0 Update 1. In the `applmgmt.log` , you see an error message such as `Failed to mount the remote storage` . The issue occurs because of Linux kernel updates that run during the patch process. The issue does not occur on fresh installations of vCenter Server 7.0 Update 1.

Workaround: Reboot the vCenter Server appliance after the update is complete.

Microsoft Active Directory Federation Services (ADFS) logins might fail after restoring a vCenter Server Appliance

If you manually add a certificate to the vCenter Server JRE truststore or modify the `/etc/hosts` file when setting up ADFS, the changes are not preserved after restoring and might cause ADFS logins to fail.

Workaround: Add the ADFS certificate to the vCenter Server JRE truststore after restoring your vCenter Server Appliance. For more information, see Import the Trusted Certificate of an External Identity Provider. Add the necessary host name mappings back to the `/etc/hosts` file after restoring your vCenter Server Appliance.

vSAN Issues

Higher than actual vSAN storage pool free space estimate might lead to unexpected storage shortages

The `freeSpace` parameter of a vSAN storage pool might not exclude disks with errors and display the unused space estimate as higher than the actual. As a result, you might see unexpected storage shortages. This issue only affects vSAN storage pools.

Workaround: Manually compute the storage capacity by disregarding the `freeSpace` value of disks with errors from the overall storage capacity provided by the `freeSpace` parameter of the storage pool.

Server Configuration Issues

You see a message Error retrieving when trying to view the status of Key Management Server (KMS) instances in the vSphere Client

In the vSphere Client, you might see a message `Error retrieving` for several minutes when trying to view Key Management Server (KMS) instances. The issue occurs when a KMS instance in a standard key provider loses connectivity. Until all network requests to the affected KMS time out, which takes around 4 minutes, you cannot see the status of any KMS instance in your system, only the error message for the key provider. After the timeout, you can see the status of all KMS instances.

Workaround: If you see the Error retrieving message, wait for 4 minutes.

Due to a default timeout setting of 2 minutes, log in to vCenter instances in Enhanced Linked Mode takes long when any of the vCenters is down

When you have a number of vCenter instances in Enhanced Linked Mode, if one of the instances is down for some reason, such as maintenance, log in to the other instances might take up to 2 minutes, which is the default timeout setting. Changing the timeout property that specifies the wait time for log in to linked vCenter instances is a complex task that requires manually editing the `LinkedVcGroup.login.timeout` property located in `vim-commons-vsphere.properties` . To simlify the task, starting with vCenter Server 7.0 Update 3l, the setting `LinkedVcGroup.login.timeout=120000` moves from `vim-commons-vsphere.properties` to the `webclient.properties` file. Editing this option allows you to reduce the wait time so that if one of the vCenter logins is taking more time, it does not affect the log in time for other instances.

Workaround: Edit `/etc/vmware/vsphere-ui/webclient.properties` and change the value of `LinkedVcGroup.login.timeout` from `120000` to a smaller value in milliseconds, but consider that a value of `<= 0` is an infinite timeout.

VMware vCenter Server 7.0 Update 3u Release Notes

This document contains the following sections

- Introduction
- What's New
- Patches Contained in This Release
- Known Issues from Prior Releases

Introduction

VMware vCenter Server 7.0 Update 3u | 31 MAR 2025 | ISO Build 24614210 Check for additions and updates to these release notes.

What's New

- VMware vCenter Server 7.0 Update 3u serves as a vehicle for VMware vSphere with Tanzu and does not deliver vCenter Server fixes.

Patches Contained in This Release

Patch for VMware vCenter 7.0 Update 3u

Download Filename	VMware-vCenter-Server-Appliance-7.0.3.02300-24614210-patch-FP.iso
Build	24614210
Download Size	6701.3 MB
md5sum	3ca90d9abb05a79c1b76ff0c573b0228
sha256checksum	483ec3c8184281e69f720ff11d0ad896fc709b1785ec20409f12360f9a83a629
PRs fixed	3479424
CVEs	N/A

Download and Installation

Log in to the Broadcom Support Portal to download this patch.

For download instructions for earlier releases, see Download Broadcom products and software.

For more information on using the vCenter Server shells, see VMware knowledge base article 2100508.

For more information on patching vCenter Server, see Patching the vCenter Server Appliance.

For more information on staging patches, see Stage Patches to vCenter Server Appliance.

For more information on installing patches, see Install vCenter Server Appliance Patches.

For more information on patching using the Appliance Management Interface, see Patching the vCenter Server by Using the Appliance Management Interface.

Known Issues from Prior Releases

vSphere Cluster Services Issues

If all vSphere Cluster Service agent virtual machines in a cluster are down, vSphere DRS does not function in the cluster

If vSphere Cluster Service agent virtual machines fail to deploy or power on in a cluster, services such as vSphere DRS might be impacted.

Workaround: For more information on the issue and workarounds, see VMware knowledge base article 79892.

System virtual machines that support vSphere Cluster Services might impact cluster and datastore maintenance workflows

In vCenter Server 7.0 Update 1, vSphere Cluster Services adds a set of system virtual machines in every vSphere cluster to ensure the healthy operation of vSphere DRS. The system virtual machines deploy automatically with an implicit datastore selection logic. Depending on your cluster configuration, the system virtual machines might impact some of the cluster and datastore maintenance workflows.

Workaround: For more information on the impacted workflows and possible workarounds, see VMware knowledge base articles 79892 and 80483.

Installation, Upgrade, and Migration Issues

Upgrade to vSphere 7.0 Update 3c might require additional steps to force a full host-sync

The supported upgrade sequence for vSphere systems is first to upgrade vCenter Server and then ESXi. However, in certain environments with ESXi hosts of version 7.0 Update 2d and later, you need to update ESXi first to 7.0 Update 3c and then vCenter Server. Such an upgrade sequence requires additional steps to force a full host-sync.

Workaround: Log in to the appliance shell as a user with super administrative privileges (for example, `root`) and follow these steps:

1. Stop the vpxd service.
2. Run the command `/opt/vmware/vpostgres/current/bin/psql -U postgres -d VCDB -c "update VPX_HOST_SYNC_GEN set master_gen=0 where host_id in (select id from VPX_HOST where product_version like '7.0.3%')"`.
3. Start the vpxd service.

Patching vCenter to version 7.0 Update 3q might fail due to unsupported TLS ciphers in the Envoy proxy configuration

During the update of a vCenter instance to version 7.0 Update 3q, some services might fail to start due to custom configuration of the TLS cipher suites in the file `/etc/vmware-rhttpproxy/config.xml` . As a result, in the vSphere Client you see a warning such as `An error occurred while starting service 'vpxd-svcs'` and the process fails. If you use the Virtual Appliance Management Interface, you see an error such as `Installation Failed - Exception occurred in postInstallHook.`

Workaround: See KB 369485 for steps how to reset the TLS ciphers to their defaults and retry the vCenter update.

Hot-patched ESXi hosts with both i40en and i40enu Intel network drivers installed might fail to configure vSphere High Availability after upgrade to vCenter Server 7.0 Update 3c

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3c adds an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. However, if you apply an ESXi hot patch that is released after vCenter Server 7.0 Update 3c and then upgrade your system to vCenter Server 7.0 Update 3c, the hot patch might not be listed in the precheck. As a result, you might not follow the proper steps to the upgrade and vSphere HA might fail to configure on such hosts.

Workaround: Upgrade the hot-patched ESXi hosts to version 7.0 Update 3c.

The vCenter Upgrade/Migration pre-checks fail with "Unexpected error 87"

The vCenter Server Upgrade/Migration pre-checks fail when the Security Token Service (STS) certificate does not contain a Subject Alternative Name (SAN) field. This situation occurs when you have replaced the vCenter 5.5 Single Sign-On certificate with a custom certificate that has no SAN field, and you attempt to upgrade to vCenter Server 7.0. The upgrade considers the STS certificate invalid and the pre-checks prevent the upgrade process from continuing.

Workaround: Replace the STS certificate with a valid certificate that contains a SAN field then proceed with the vCenter Server 7.0 Upgrade/Migration.

Problems upgrading to vSphere 7.0 with pre-existing CIM providers

After upgrade, previously installed 32-bit CIM providers stop working because ESXi requires 64-bit CIM providers. Customers may lose management API functions related to CIMPDK, NDDK (native DDK), HEXDK, VAIODK (IO filters), and see errors related to **uwglibc** dependency.

The syslog reports module missing, "32 bit shared libraries not loaded."

Workaround: There is no workaround. The fix is to download new 64-bit CIM providers from your vendor.

Patching to vCenter Server 7.0 Update 1 from earlier versions of vCenter Server 7.x is blocked when vCenter Server High Availability is enabled

Patching to vCenter Server 7.0 Update 1 from earlier versions of vCenter Server 7.x is blocked when vCenter Server High Availability is active.

Workaround: To patch your system to vCenter Server 7.0 Update 1 from earlier versions of vCenter Server 7.x, you must remove vCenter Server High Availability and delete the passive and witness nodes. After the upgrade, you must re-create your vCenter Server High Availability clusters.

Migration of a 6.7.x vCenter Server system to vCenter Server 7.x fails with an UnicodeEncodeError

If you select the option to import all data for configuration, inventory, tasks, events, and performance metrics, the migration of a 6.7.x vCenter Server system to vCenter Server 7.x might fail for any vCenter Server system that uses a non-English locale. At step 1 of stage 2 of the migration, in the vSphere Client, you see an error such as:

```
Error while exporting events and tasks data: …ERROR UnicodeEncodeError: Traceback (most recent call last):
```

Workaround: You can complete the migration operation by doing either:

- Select the default option **Configuration and Inventory** at the end of stage 1 of the migration. This option does not include tasks and events data.
- Clean the data in the events tables and run the migration again.

If a Windows vCenter Server system has a database password containing non-ASCII characters, pre-checks of the VMware Migration Assistant fail

If you try to migrate a 6.x vCenter Server system to vCenter Server 7.x by using the VMware Migration Assistant, and your system has a Windows OS, and uses an external database with a password containing non-ASCII characters, the operation fails. For example, Admin!23迁移. In the Migration Assistant console, you see the following error:

```
Error:Component com.vmware.vcdb failed with internal errorResolution:File Bugzilla PR to VPX/VPX/vcdb-upgrade
```

Workaround: None

During an update from vCenter Server 7.x to vCenter Server 7.0 Update 1, you get prompts to provide the vCenter Single Sign-On password

During an update from vCenter Server 7.x to vCenter Server 7.0 Update 1, you get prompts to provide vCenter Single Sign-On administrator password.

Workaround: If you run the update by using the vCenter Server Management Interface, you must provide the vCenter Single Sign-On administrator password.

If you run the update by using software-packages or CLI in an interactive manner, you must interactively provide the vCenter Single Sign-On administrator password.

If you run the update by using software-packages or CLI in a non-interactive manner, you must provide the vCenter Single Sign-On administrator password by an answer file in the format

```
{ "vmdir.password": "SSO Password of Administrator@<SSO-DOMAIN> user" }
```

Smart Card and RSA SecurID authentication might stop working after upgrading to vCenter Server 7.0

If you have configured vCenter Server for either Smart Card or RSA SecurID authentication, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057 before starting the vSphere 7.0 upgrade process. If you do not perform the workaround as described in the KB, you might see the following error messages and Smart Card or RSA SecurID authentication does not work.

"Smart card authentication may stop working. Smart card settings may not be preserved, and smart card authentication may stop working."

or

"RSA SecurID authentication may stop working. RSA SecurID settings may not be preserved, and RSA SecurID authentication may stop working."

Workaround: Before upgrading to vSphere 7.0, see the VMware knowledge base article at https://kb.vmware.com/s/article/78057.

You might not be able to apply or remove NSX while you add ESXi hosts by using a vSphere Lifecycle Manager image to a cluster with enabled VMware vSphere High Availability

If you start an operation to apply or remove NSX while adding multiple ESXi hosts by using a vSphere Lifecycle Manager image to a vSphere HA-enabled cluster, the NSX-related operations might fail with an error in the vSphere Client such as:

```
vSphere HA agent on some of the hosts on cluster <cluster_name> is neither vSphere HA master agent nor connected to vSphere HA master agent. Verify that the HA configuration is correct.
```

The issue occurs because vSphere Lifecycle Manager configures vSphere HA for the ESXi hosts being added to the cluster one at a time. If you run an operation to apply or remove NSX while vSphere HA configure operations are still in progress, NSX operations might queue up between the vSphere HA configure operations for two different ESXi hosts. In such a case, the NSX operation fails with a cluster health check error, because the state of the cluster at that point does not match the expected state that all ESXi hosts have vSphere HA configured and running. The more ESXi hosts you add to a cluster at the same time, the more likely the issue is to occur.

Workaround: Deactivate and enable Sphere HA on the cluster. Proceed with the operations to apply or remove NSX.

After an upgrade of a vCenter Server 7.0 system, you cannot see the IP addresses of pods in the vSphere Pod Summary tab of the vSphere Client

If you upgrade your vCenter Server 7.0 system to a later version, you can no longer see the IP addresses of pods in the **vSphere Pod Summary** tab of the vSphere Client.

Workaround: Use the Kubernetes CLI Tools for vSphere to review details of pods:

1. As a prerequisite, copy the pod and namespace names.
   - In the vSphere Client, navigate to **Workload Management** > **Clusters.**
   - Copy the IP displayed in the **Control Plane Node IP Address** tab.
   - You can navigate to `https://<control_plane_node_IP_address>` and download the Kubernetes CLI Tools, `kubectl` and `kubectl-vsphere`.
     Alternatively, follow the steps in Download and Install the Kubernetes CLI Tools for vSphere.
2. Use the CLI plug-in for vSphere to review the pod details.
   a. Log in to the Supervisor cluster by using the command
      ```
      kubectl vsphere login --server=https://<server_adress> --vsphere-username <your user account name> --insecure-skip-tls-verify
      ```
   b. By using the names copied in step 1, run the commands for retrieving the pod details:
      ```
      kubectl config use-context <namespace_name>
      ```
      and
      ```
      kubectl describe pod <pod_name> -n <namespace_name>
      ```

As a result, you can see the IP address in an output similar to:

```
$ kubectl describe pod helloworld -n my-podvm-ns ...

Status: Running

IP: 10.0.0.10
```

```
IPs:
IP: 10.0.0.10 ...
```

Upgrading a vCenter Server with an external Platform Services Controller from 6.7u3 to 7.0 fails with VMAFD error

When you upgrade a vCenter Server deployment using an external Platform Services Controller, you converge the Platform Services Controller into a vCenter Server appliance. If the upgrade fails with the error `install.vmafd.vmdir_vdcpromo_error_21` , the VMAFD firstboot process has failed. The VMAFD firstboot process copies the VMware Directory Service Database (data.mdb) from the source Platform Services Controller and replication partner vCenter Server appliance.

Workaround: Deactivate TCP Segmentation Offload (TSO) and Generic Segmentation Offload (GSO) on the Ethernet adapter of the source Platform Services Controller or replication partner vCenter Server appliance before upgrading a vCenter Server with an external Platform Services Controller. See Knowledge Base article: https://kb.vmware.com/s/article/74678

vCenter Server system upgrades fail in the pre-check stage

Upgrades of your vCenter Server system might fail in the pre-check stage due to a limit in the authorization (Authz) connections. In the `/var/log/vmware/vpxd-svcs/vpxd-svcs*.log` file you see entries such as:

`Session count for user [after add]: <DOMAIN-NAME>\machine-xxxx is 200Session limit reached for user: <DOMAIN-NAME>\machine-xxxx with 200 sessions.`

You might also see delayed response from the vSphere Client to load the inventory.

Workaround: Restart vmware-vpxd-svcs in your vCenter Server system by using the command `service-control --restart vmware-vpxd-svcs` . Use the command only when no other activity runs in the vCenter Server system to avoid any interruptions to the workflow. For more information, see VMware knowledge base article 81953.

Upgrading vCenter Server using the CLI incorrectly preserves the Transport Security Layer (TLS) configuration for the vSphere Authentication Proxy service

If the vSphere Authentication Proxy service (`vmcam`) is configured to use a particular TLS protocol other than the default TLS 1.2 protocol, this configuration is preserved during the CLI upgrade process. By default, vSphere supports the TLS 1.2 encryption protocol. If you must use the TLS 1.0 and TLS 1.1 protocols to support products or services that do not support TLS 1.2, use the TLS Configurator Utility to enable or deactivate different TLS protocol versions.

Workaround: Use the TLS Configurator Utility to configure the `vmcam` port. To learn how to manage TLS protocol configuration and use the TLS Configurator Utility, see the *VMware Security* documentation.

You do not see a precheck error when patching to vCenter Server 7.0 Update 3c by using CLI

Due to the name change in the Intel i40en driver to i40enu and back to i40en, vCenter Server 7.0 Update 3c adds an upgrade precheck to make sure that ESXi hosts affected from the change are properly upgraded. In some cases, if such hosts exist in your system, patching from an vCenter Server version earlier than 7.0 Update 3 to a version later than 7.0 Update 3 by using CLI might fail with the error `Installation failed. Retry to resume from the current state. Or please collect the VC support bundle..`

However, instead of this error, you must see the precheck error message.
